TEMPERATURE OF THE INSANE, ESPECIALLY IN ACUTE MANIA AND MELANCHOLIA.<sup>1</sup>

BY WALTER CHANNING, M.D.

In looking over textbooks and other works on insanity comparatively little will be found on this subject. Before the time of Wunderlich and the general use of the thermometer in disease this was, of course, not surprising, but at the present time we might fairly infer that if little reference is made to the thermometer it is because it has been thoroughly tried and given up as of little value.

How correct this inference is I will not say, though I believe that to a certain extent it is a true one.

To give a little clearer idea of the position of some of the leading authorities, I will briefly refer to a few of them. Bucknill and Tuke in their last edition have something to say on the temperature in general paralysis, but elsewhere give no systematic thermometric observations. Blandford in his last edition refers to the diagnostic value of the temperature in the early stage of acute delirium mania, and also quotes Mickle and Crichton Browne as to the temperature of general paralysis, but this is about all he says. Sankey (last edition) chiefly refers to the value of taking the temperature to determine the possibility of intercurrent disease in critical cases. Griesinger fully recognized the physical changes taking place in the insane, though he said nothing of temperature. In 1867, when his valuable work was published, but little attention had been paid to the temperature in insanity. From his careful system of elaborating every point of any importance, he probably would have considerable to say on the subject to-day.

Krafft-Ebing, Clouston, Savage, Spitzka, and other writers, in their textbooks, while they speak of the temperature in insanity as being of more or less significance, do not enlarge upon it in detail and give no statistics or observations.

Bearing these facts in mind, it is not to be wondered at that the student of mental disease is not at first led to direct his attention to the clinical use of the thermometer. If he has been drilled by hospital practice of a general nature to give consideration to the bodily temperature, he will perhaps be earlier led to think of it in insanity. Otherwise he may wait until he comes across occasional essays on the subject in the scattered journalistic literature of insanity, which may inspire his ambition.

In my own case, though I recognized the value of thermometric observations in many diseases, I felt from what I had read on the subject, and seen of the practice of others in cases of insanity, that any evidence furnished by the thermometer, excluding general paralysis, was of little value, chiefly negative in character, and hardly worth taking much trouble about. I was in the habit of taking an occasional temperature, but usually in a case of suspected complication, or where there was very unusual elevation of temperature as indicated by a hot skin, flushed cheeks, etc.

Nearly four years ago I began, as a matter of routine practice, to take temperatures morning and evening for some weeks, after a patient came under treatment, provided it was not difficult to do and the patient did not object.

I used the axilla, leaving the thermometer in place for six to ten minutes. My results were fairly satisfactory, but I found objections to this method, which were as follows: (1) I was obliged to make the observation usually when the patient got up or went to bed, as it was liable to excite or irritate him at other times. (2) The thermometer was liable to slip out of place after a few minutes. (3) I could not easily keep it in place myself, as efforts in this direction would sometimes annoy or excite the patient.

These objections, which were the principal ones I met with, are much greater with the insane than the sane, as can readily be seen. The hours of rising and going to bed are inconvenient ones for the physician to be present, but insane persons object frequently to being undressed or disturbed during the day. As, in most cases, unless of a severe type, insane patients do not remain in bed, we cannot as in a fever quietly take a temperature at any hour during the day. There are furthermore the queer ideas, partly or wholly delusive in character, which may be originated or fostered by exposing patients to take temperatures or taking them before rising or after going to bed.

For these reasons a physician is often obliged to let the nurse take the axillary temperature of an insane patient. If this be done, it is necessary to rely more on the nurse than is desirable for reliable results. There are always the dangers that the nurse may not rightly place the thermometer and, even if rightly placed, may not leave it in position for a sufficiently long time. Clouston,<sup>2</sup> in the series of observations made by him, adopted four minutes as the length of time necessary to leave the thermometer in the axilla. After this period of time he thinks there is little increase, and patients are often so much excited that a minimum of length of time must be adopted. Tambroni<sup>3</sup> thinks that twenty minutes is the right time for an axillary observation. Undoubtedly twenty minutes are preferable to four, but unless the cases were selected, it would be difficult to keep insane patients quiet for such a long time.

In view of the above objections, I was led to adopt the mouth as a better place to take temperatures in the insane than the axilla, and so far have been satisfied with the results.

The chief objection to the mouth is the possibility of a violent patient breaking the thermometer between his teeth, either by accident or design, and this happened to me in one case, but such a danger can usually be avoided by care.

When a patient is too violent to insert the thermometer in the mouth with safety, I have used the rectum. The objection of exposing a patient holds good when the rectum is used and perhaps to a greater degree than in the case of the axilla. Otherwise a temperature can be taken in this place

<sup>1</sup>Read before the Boston Society for Medical Observation, May 1, 1885.

<sup>2</sup>Observations on the Temperature of the Insane. By F. S. Clouston.

<sup>3</sup>Contributo allo studio delle Temperature ne li alienati. Del Dott. Ruggero Tambroni. Rivista Sperimentale, 1881-85.

with accuracy, as is well known, and in my experience with comparative ease. The patient is placed on a bed partly on the anterior portion of one side, with the legs somewhat flexed. One nurse holds the arms and another the legs.

The advantages of taking temperatures in the mouth are: (1) The accessibility it offers at all hours. (2) Its entire freedom from the objection of exposing the person. (3) The possibility of accurate observations both at the hands of physician and nurse. The latter advantage is an important one, for while there may be doubt in axillary observations even if taken by the physician, this doubt is hardly possible in the mouth. The only condition to be observed is that the thermometer be kept in the mouth for a given length of time. The chances of not placing the thermometer properly and of its slipping a little by a movement of the patient are much less in the mouth than in the axilla. (4) The shorter period of time required for taking the temperature in the mouth. In the axilla probably fifteen to twenty minutes is none too long a time to get the maximum degree of temperature, whereas in the mouth six to ten minutes will suffice.

A general objection to the use of the thermometer in insane persons is that they occasionally may develop delusions in regard to it, as they do in regard to almost any unusual procedure. Sometimes it is regarded as an instrument to introduce poison or electricity, or to produce heat or cold, or for the purpose of performing a surgical operation, as in a recent case of my own. It may be a means of torture, or as Clouston has reported may, on the other hand, have a direct curative effect.

These general disadvantages I have found to usually disappear after the thermometer had been regularly employed for a few days.

In thermometric observations, as we all well know, the number must be large and the conditions under which they are made absolutely uniform to possess the largest degree of value. Thus Wunderlich states<sup>1</sup> that the number of cases he studied amounted to nearly twenty-five thousand, and the number of single observations to some millions. Tamburini reports four thousand observations. Clouston made two thousand observations on three hundred and five patients.

My own observations made either in the mouth or rectum exceed one thousand considerably; but for convenience I shall call them only this number. Together with my earlier axillary observations they possess interest, though the number is so small that they can be regarded only as a beginning of a series, which I hope in time will be considerably expanded.

Clouston took the temperatures of all the patients in the asylum of which he was the then superintendent; not continuously for a number of weeks, but at irregular intervals. He thought that by this method he could get at the variations and peculiarities in the cases under examination in the most satisfactory manner. By this method he was able to show the characteristic differences in temperature in different forms of insanity as well as the prevailing type of temperature at certain stages of the different forms.

My own observations have taken, and will in the future take, a different direction; that is, I shall begin with all patients coming under treatment, and regularly and continuously until discharge take their morning and evening temperatures, keeping careful notes of their mental condition during this period. By such a method I shall hope to show, taking the temperature of the entire period of the disease, any relation that may exist between changes in temperature and changes in the mental condition, and also how the variations and fluctuations in temperature in an attack of mental disease generally differ from those found in other diseases and in health. I can further show, taking the entire period of the attack, whether there are certain definite characteristics marking the different periods or stages of the different forms of insanity as a whole, and whether the diets of Wunderlich in regard to the "fastigium" or "acme" stage in regard to ordinary diseases holds good of this period in attacks of insanity.

In this period, he says, "characteristic data for a correct diagnosis are presented in three ways: from the height of the temperature; from its successive alterations; from the duration of this stage. By the elevation of temperature, its continuance at abnormal heights, and its deviations from the normal type, we learn the intensity and degree of danger of a disease. On the other hand, when the elevation of temperature is moderate, the duration of the maxima short, and the remissions early, we judge that the disease is of a mild type. Irregularities in the course of the temperature, even when they indicate an abatement of fever, are favorable only in special cases. A rise of temperature toward the end of this stage generally betokens some complication."<sup>5</sup>

How far these and other assertions of Wunderlich are found to hold good in cases of insanity can be ascertained, as I have said before, only after continuous observation of many cases. The following cases throw some light on certain points of the subject.

#### ACUTE MANIA. PROBABLE MANIACAL STAGE OF FOLIE CIRCLAIRE.

CASE I. MRS. A., thirty-seven years old. Married, and has had two children. Inherits a nervous, excitable temperament. Has had two previous attacks: one of mania and one of melancholia. Is now suffering from an attack, which has become fully developed only within seventy-two hours. On admission somewhat excited, and inclined to ramble from one subject to another, though talking most of the time coherently, yet constantly in an exalted manner to herself. Checks slightly flushed; pulse 111; tongue heavily coated; reduced in weight. Temperature not taken on the first day.

Second day. After a poor night's sleep more excited in language and inclined to throw herself about in the room, though showing indications of weakness. The nurse was directed to keep her in bed. Temperature 99° and pulse 120 in the morning, and 99.2° and the pulse 120 at night.

Third day. Mental condition rather worse, the morning temperature being 99°, pulse 120, and at

<sup>1</sup> Wunderlich's *Medic. Thermometry*, abridged by E. Seguin, M.D.

<sup>5</sup> Seguin's Wunderlich, p. 17.

evening 100°, pulse 120, a rise of one degree in temperature during the day.

Fourth day. Much more mental excitement; conversation confused, incoherent, but constant and very loud and interspersed with occasional songs. Motor excitement also increased. Tongue dry and heavily covered with a dirty brownish coat. Temperature 101.4° and pulse 132 in the morning, and 100° and the pulse 120 at night. The mental and motor excitement had somewhat diminished during the day. For twelve days the temperature then ranged from 99° to 101° (the pulse ranging from 126 to 140), showing usually an average difference of a degree between morning and night. It was almost always higher at night than in the morning, during these twelve days, until the last two, when it was slightly lower at night.

On the sixteenth day, the evening temperature was 99.4°, pulse 125. The mental condition was at this time one of considerable excitement; rambling and incoherent conversation was still incessant, except during sleep, which was obtained only by sedatives in free doses. Every muscle was in a state of activity, and the patient was kept in bed with some trouble.

On the morning of the seventeenth day, after a noisy, restless, and nearly sleepless night, in spite of large doses of quieting medicine, the conditions of the previous night were present in an intensified form, and the temperature was 101.1° and the pulse 130. During the day the general excitement increased, and was so great at night that the temperature was taken in the rectum and was found to be 102.3° and the pulse 138.

On the morning of the eighteenth day the temperature was 112.5°, pulse 126. General excitement about as the day before. At night the temperature reached 103.1°; pulse not recorded.

During the night of the eighteenth day there was a fall to 101.2°, pulse 126, and I hoped that a change for the better had taken place. The general mental excitement, however, and the great constitutional disturbance continued as before. By evening a rise to 103.1° (pulse of 138) had taken place.

The morning of the twentieth day, after a night of wild and sleepless excitement, showed an exacerbation of temperature of more than a degree, the thermometer recording 101.5°, the pulse reaching 146. The tongue was dry and brown, the lips parched, the pulse very weak, speech was low and muttering, but incessant, and the motor excitement was still almost constant. The patient at this time swallowed liquid nourishment freely, which was the one indication of reaction that I saw.

During much of the day I kept the patient wrapped in a wet sheet, partly, I might say, as a last resort. At night the temperature had fallen to 103.1°. The pulse, however, at five o'clock on this day was not to be counted: in fact, it was almost imperceptible, and I felt that the patient could only live for a few hours longer. She was still willing to take the food, however, and with stimulants it was pressed on her. After a short time the pulse showed improvement. The wet pack was continued until one o'clock of the twenty-first morning, when the temperature had fallen to nearly 101°, and it was removed.

On the morning of the twenty-first day the temperature had fallen to 99.4° F., and the pulse was 114 and very weak. During the twenty-four hours the patient took five pints of milk, ten eggs, and four ounces of brandy with little difficulty. The excitement was decidedly less than the previous day. The evening temperature was 100.3° F. and the pulse 132.

On the twenty-second day the patient again began to show symptoms of great excitement and general disturbance, with a parched, brown tongue, picking at the bedclothes, etc. The morning temperature was 101° F., and the pulse 126. She was kept for five hours during the day in the wet pack. At night the temperature was 101.3° F., pulse 138. During this twenty-four hours the patient took fourteen eggs, five pints of milk, eight drachms of Valentine's beef-juice, and four ounces of brandy.

The next morning (twenty-third day) the temperature was 103° F., pulse 126. The wet sheet was again applied for five hours, until the temperature fell to 100.4° F. The general excitement was considerable during the day.

At night the temperature was 102° F., pulse 138, and the wet sheet was applied until there was a fall of a degree. During the twenty-third day the patient took three quarts of milk, thirteen eggs, six drachms of Valentine's beef-juice, and one and a half ounce of brandy.

On the morning of the twenty-fourth day the temperature had fallen to 99.2° F. (pulse 128), a difference of more than two and a half degrees. At night there was a still further remission to 99.1° F., pulse 126.

On the morning of the twenty-fifth the temperature fell to the normal point, with a pulse of 111, and this was the first time since admission that the temperature had been below 99° F.

Accompanying the remission there was great prostration, with weak pulse and inability to retain food, and I feared that there might be still further depression and collapse. For two days the patient slept almost continuously, and the temperature remained at about 99° F., with a pulse ranging from 114 to 120.

This low temperature continued for six days, or until the thirty-sixth day, when it rose from 99.1° F. in the morning to 101.1° F. in the evening, the pulse rising also from 111 to 132. The wild delirium, disjointed talking, and the motor excitement, which had been somewhat in abeyance, became much increased. During the quiet days the patient had taken little food, but now, in her excited condition she was able to assimilate it, and on this day took ten eggs and three quarts of milk.

At this time she was with difficulty kept in bed. She was inclined to tear the bedclothing, was often noisy both day and night, slept only two or three hours in the twenty-four, and soiled and wet the bed, or it was necessary to use the catheter.

On the thirty-sixth day, or after five days of excitement, the temperature began to fall from 100.2° F., which was nearly the highest point it had reached during the five days, and on the evening of the thirty-seventh day it again reached the normal point, with a pulse of 102. A short period of quiet, with less prostration than before, now followed for a few days.

After this time the temperature ranged from normal to 99.4° F., only on the forty-sixth, one hundred and thirty-seventh, and one hundred and eighty-fourth days going above 100° F., when it respectively reached 100.1°, 100.1°, and 100.3° F. Each of these slight exacerbations represented a period of considerable increased excitement, which at the time seemed like a relapse.

About the forty-eighth day the patient began to sit up, and on the fifty-eighth day she went outdoors for the first time.

As a rule the normal type of higher temperature at night than in the morning prevailed. During the last three weeks the rule was lower at night than in the morning.

The mobility of the temperature for the first twenty-four weeks was very marked. The most curious fluctuations presented themselves from day to day. For the last six weeks, however, the differences between night and morning became less and less marked.

The temperature of this patient was taken for a continuous period of thirty weeks; in the morning between eight and nine, and at night at six o'clock.

After the first six weeks slight improvement was manifested, and then by almost imperceptible degrees she grew better, being discharged as recovered on the three hundred and thirty-seventh day.

This case showed a clear connection between the mental changes and the temperature changes. By following the chart it was possible to tell whether the patient was quiet or excited, and to how great a degree, and with much greater accuracy than if it had not been kept. It kept every one more keenly on the alert, too, in carrying out therapeutic measures, as it practically showed in black and white the seriousness of the disease. I am certain that I was more watchful than I should have otherwise been, for without the thermometer I could not have realized the height of the temperature, and I should not have forced the food and used the wet sheet as actively as I did.

It may undoubtedly be said in reference to this case that the temperature possesses no characteristics which would make it pathognomonic of acute mania. While this is true, it still possesses quite definite qualities. The "initial" stage was passed before admission, the second, or "fastigium" was just beginning. This proceeded for three weeks. A maximum point was then reached of 101.2° and deferescence supervened by "lysis" occupying a period of five days, when the temperature touched normal. An "epicritical" period followed, if we choose to call this a period "in which the temperature returns to normal through increased mobility and a sort of fickleness. Isolated and apparently causeless rises of 4° to 6° F., relapses, and secondary affections show themselves in this period, whose illimitable duration merges in true convalescence."<sup>6</sup>

This period lasted for upward of two weeks.

The illimited period spoken of followed, during which the temperature showed a persistent tendency to vary less and less. There was diminishing mobility, which was for a long time a characteristic. Occasionally there would be isolated

periods of rise of temperature, easily accounted for, however, by the mental and motor excitement.

Taking the long period following what I have called the "epicritical period," in the language of Wunderlich, the chart demonstrates a very slow but gradual return to decided improvement or convalescence.

CASE II. Mania. Mrs. B., twenty-five years of age, married, one child. No heredity, though parents were nervous. This attack followed her confinement about eighteen months before admission. The case has been one of severity since the beginning. The excitement has been considerable, both day and night. Has a great variety of delusions, about which she talks continually. Keeps her body in motion most of the time, and is continually on her feet, in consequence of which they are swollen. Eats and sleeps pretty well. Physical condition is poor. Is reduced in flesh, very pallid, tongue heavily coated, pulse 110 and weak. Looks worn and exhausted. Very filthy in habits. A persistent masturbator.

The first night the temperature was 98.3°. The second morning, after a fair night, it had gone up to 100.3° with a pulse of 140. The eighth day the thermometer marked 102.2°, pulse 123. This was at night. On the eleventh morning, the temperature was 99.1°, pulse 120. At night there was a rise to 102.2°, pulse 111. At this time the patient was talking all her waking hours, and was usually on her feet, unless held down. Some portion of the day she was inclined to talk low and quietly, others excitedly, ate her food well, slept fairly well. Drove out frequently. Made no complaint of any pain, and no complication of any kind was suspected.

On the eighteenth and twenty-first days the temperature again reached 102°. It would be higher as a rule at night than in the morning. The fall between night and morning would sometimes be as much as two and one-half degrees.

On the twenty-second day the temperature reached 102.1°, pulse 132, at night. The record of the remaining days was as follows:—

On the 23d, a.m., 101.1°; p.m., 102.2°. 24th, 100°; 103°. 25th, 100.2°; 102.2°. 26th, 100.2°; 101.4°. 27th, 100.4°; 101.1°. 28th, 102.4°; 104.1°. 29th, 101°; 101.2°. 30th, 101.2°; 104°. 31st, 102.3°; 104.3°. 32d, 102.3°; 104.4°. 33d, 105.1°; 105°. 34th, 101.2°; 104°. 35th, 101.3°; 104.1°. 36th, 105°; 102.3°. 37th, 101.3°; 102.2°. 38th, 100°; 103.1°. 39th, 101.1°; 103.1°. 40th, 100.3°; 103.1°. 41st, 100.1°; 104°. 42d, 102.1°; 104°. 43d, 101.1°; 104°. 44th, 102°; 104.4°. 45th, 103.3°; 104.1°. 46th, 105.1°; 106.2°. 47th, 105.1°; 105°. 48th, 105.1°; 106.1°.

The pulse from the 23d to the 48th day ranged from 96 to 138, reaching the lowest figure only once and averaging perhaps 120.

The patient died on the forty-eighth day.

Up to the end the mental condition showed little change. Her delusive ideas were always the constant theme of her conversation, and so engrossed her mind that she made no complaint of pain or ache, and up to the last four or five days was quite able to keep on her feet. Other than a warm skin and quick pulse, no symptoms not sufficiently

<sup>6</sup> Seguin's Wunderlich, p. 129.

accounted for by the mental disease would have attracted any notice had not the thermometer been employed daily.

The patient's appetite was good almost to the end, and she could take food on the last day. The bowels were inclined to looseness, but not too much so. She had a slight, hacking cough, but breathed until the last two weeks without difficulty.

The elevated temperature was the only indication that at first alarmed me. The mental disease could easily explain this for the first three weeks. After this, however, the continued high temperature and its extraordinary mobility between night and morning made me feel that there was a hidden complication. The physical signs pointed toward the end to phthisis, and the temperature was also indicative of this complication. From the fortieth to the forty-fifth day there were two hæmorrhages, one considerable one at night. Considerable pus was coughed up on several occasions. There was no autopsy.

This case demonstrated to a remarkable degree the utility of the thermometer in insanity, if complications exist. The patient's skin did not appear very warm and entirely deceived me as to its heat. The cheeks were often flushed at night, a hectic flush setting in pretty regularly about three o'clock, but the skin never suggested a higher temperature than 100 to 102 degrees. I always took this patient's temperature in the rectum, but sometimes doubting the correctness of the observations, would try other thermometers in the mouth and axilla, but with a similar result. The axillary temperature was a degree to a degree and one-half less than in the rectum.

The "amphibolic" stage of Wünderlich<sup>2</sup> was well marked in this case, beginning apparently about the twenty-seventh day. There was, at the end of this stage, a characteristic final rise of temperature or "perturbatio critica." The great irregularities in temperature were unfavorable from the start. Thus the temperature, by itself, indicated pretty surely a fatal result.

Clouston<sup>3</sup> speaks of the temperature of phthisical insanity being higher than any other form of insanity. This would apply also to a case in which phthisis was developed in the course of an attack of insanity.

(To be concluded.)

## A CASE OF TUBERCULAR MENINGITIS; DEATH: AUTOPSY.

By HENRY E. JACQUES, M.D., OF MILTON.

The patient was a boy, five years old. He was always well and strong, except for a tonsillitis, of which he had frequent attacks. Family history good on both sides.

On December 20, 1884, I was called to see him, and obtained the following history: He had come out to Milton looking and feeling as well as ever. On December 23d, while endeavoring to climb into bed, he fell and struck the back of his head. He

cried afterward, but the blow left no mark, and no more was thought of it. The next day, while playing, he fell and struck his forehead, but the blow was no more serious than he had often had before. That evening, Christmas eve, he went to a children's party, but ate nothing unusual, went to bed early, and slept all night. Seeing, and playing with, so many children was unusual for him, but he did not seem excited by it. For a day or two afterward he was constipated and somewhat fretful, both of which conditions were remarkable for him.

On December 29th, the date of my first visit, he had a slight follicular tonsillitis. His pulse and temperature were normal; cheeks flushed; eyes dull; pupils normal. His head was slightly hot, and he was dull and drowsy. He had had no defecation for two days. I prescribed for his throat and his bowels, and told the family that he was not very sick, though I did not like the drowsiness, which, they said, was unusual. The next day his bowels moved, and I heard no more from him for several days, and thought they had probably taken him back to Boston. On January 2d they sent for their family physician, Dr. W. L. Richardson. He found the child still drowsy and again constipated, but no other symptoms. His throat was not nearly as bad as in his former attacks. He ordered cathartics, to be followed, if necessary, by injections. That evening I was again sent for. I found that the constipation was not relieved, and that the drowsiness had increased to such an alarming extent that he had to be roused before answering questions. His head was hot, and he complained of some pain in the back of his head. His face was flushed, and the eyes vacant and staring. Pulse 64 and strong, and the temperature 99° F. The bowels were moved by injections, and he passed water, though with difficulty. I told the family that there was something more than mere constipation, and advised them to send for Dr. Richardson early in the morning. During the night he slept only at intervals. Vomited once. One defecation, coming away with considerable flatus. Passed water twice freely. He moved his left leg spasmodically, and clenched his hands occasionally. He was uneasy, and moaned. Head hot. Pulse at times intermittent. Gradually he became more and more drowsy, and finally relapsed into a state of unconsciousness.

In the morning I saw him with Dr. Richardson. A careful examination revealed nothing abnormal in the chest or abdomen. The child was completely unconscious. Pupils normal. Temperature 100.6°; pulse 108; respiration 30.

We told the family that the case was very serious, that it was probably some form of meningitis, and advised them to send for Dr. T. M. Rotch. An ice-bag was applied to the head, and enemata of one ounce of milk and one drachm of brandy ordered every two hours.

In the evening Dr. Rotch, on examination, found no new symptoms except a slight congestion in the right ear in the neighborhood of the malleus. On the back, over the right apex, there was a slight elevation of pitch on percussion, but no other physical signs. Temperature 101.2°; pulse 89, and strong.

Dr. Rotch agreed that the only diagnosis possible at this time was a probable meningitis, though it

<sup>2</sup>Seguin's Wünderlich.

<sup>3</sup>Observations on the temperature of the insane.

<sup>4</sup>Read, by invitation, before the Obstetrical Society of Boston, March 11, 1885.

was possible that the right apex might develop new signs on further examination, and the symptoms be due to a hidden pneumonia.

During the day there was considerable twitching of the arms and legs, chiefly the right side, lasting from ten to twenty minutes, the chest being slightly raised. The pupils were slightly contracted and alike.

During the night he drew his right hand across the face with a quick, trembling motion, the right leg being drawn up and the whole body trembling. Occasional moaning and sighing respiration. Temperature, pulse, and respiration not much above normal. When the lips were bathed he partly opened his eyes and made an effort to swallow. Pupils sometimes contracted, sometimes dilated, cheeks flushed, tongue and lips dry. All enemata retained.

Dr. C. J. Blake, having been asked to examine the condition of the ears, found a slight congestion in the posterior canal of both ears, and also in the neighborhood of the right malleus. Dr. Blake thought that the congestion was merely a symptom of the meningeal congestion, and not the cause of the disease. When the speculum was inserted the patient showed signs of consciousness, slightly moving the eyebrows and facial muscles.

On January 6th Dr. S. G. Webber was asked to see the child in consultation. After a careful examination he decided that it was undoubtedly a case of meningitis. Taking into consideration the history of the falls and the blows on the head, and the excitement of the children's party afterward, he thought it probably a simple acute meningitis, though there was a possibility of its being tubercular. He recommended the trial of the iodide of potash. The congestion in posterior canals of both ears had diminished considerably. Pain was evidently caused by the examination.

During the next few days the condition varied but little. The enemata were almost all retained. The bowels moved once or twice daily, and the urine was passed regularly. The eyes, usually closed, were occasionally opened, with the eyeballs moving from side to side. The respiration sighing, interrupted, occasionally almost inaudible, then for a time noisy. At times the breathing was suspended for several seconds, bright red spots appearing on the cheeks, which disappeared when respiration was resumed. Patient moaned occasionally, and there was some moving and twitching of the extremities, though no convulsion. Pulse fair, though at times intermittent. The temperature, pulse, and respiration are all noted on the accompanying chart, so I will not recount here the daily variations. The extremities of the right side were absolutely motionless, and did not respond to the usual tests.

January 9th. The extremities became cold, the face very pale, and the pulse imperceptible. This condition lasted fifteen minutes, when he improved in appearance. During the night the breathing grew very rapid, he was restless, moved the left arm continually, and moaned. After some time he opened his eyes, looked round the room, and then became quiet and slept. The next day he was more unconscious, and the fingers were flexed with a very

strong contraction of the muscles. Breathing was more difficult, with the nostrils widely dilated at every breath. During the night he seemed fully conscious for some time, swallowed water without difficulty, and the eyes wide open.

January 11th. Ptosis of right eyelid. The pulse irregular, compressible, and intermittent. The left arm was occasionally raised to the head with a quick, spasmodic motion, the child moaning as if distressed meanwhile. Later, his eyes were fixed, pupils dilated, nostrils expanded, and bluish color around nose and mouth. The breathing was very difficult. During an attack of this kind he had every appearance of being moribund, and each attack was thought to be his last. One of the most remarkable features of the case was the fact that the change from day to day was almost imperceptible, and to one who did not see the child it is almost impossible to give an adequate idea of his condition.

January 12th. The pupils of both eyes were much dilated. The right eye was almost motionless, with ptosis of the right lid, while the left eye moved rapidly from side to side in a circle. The face was livid, with the hands mottled with bright red spots. Later, the left eye became quiet, with a slightly contracted pupil. The next day the movements of the left eye were repeated, the right pupil being dilated and the left contracted. During all this time the enemata were retained, the bowels moved, and the urine was passed. The pulse was so weak that at times it could not be felt at all at the wrist, and the breathing was at times inaudible and almost imperceptible. Respiration sighing. Dr. Richardson and I agreed that it was a case of probable tubercular meningitis, and held out no hope whatever to the family.

January 17th. There was a slight discharge of pus from the mouth, and also from the left eye. During the next day his breathing grew more and more difficult, and it seemed as if he could not possibly last much longer. In the evening, however, his respiration was much easier, and his whole appearance improved. His breath was very offensive, and there was a loud bubbling sound in the throat.

January 19th. The right nostril was much more dilated during inspiration than the left. The forehead was shiny, slightly edematous, and the veins plainly mapped out. Occasionally he moved his right hip-joint and shoulder, which had been motionless for days. There was another slight discharge of pus from the mouth, and when his lips were wiped he seemed more sensitive to touch than before. During the night his left arm and leg were constantly moved, and he moaned as if in pain. Forehead still edematous. During the next night he was in a state of deep coma for four hours, then drew a deep sigh and seemed more conscious afterward. Pulse soft, intermittent, and fluttering.

January 20th. He partly opened and shut his right eye, which was very sensitive to light. Breathing was difficult and noisy, and the face covered with perspiration. At 10 p.m. sighing respiration began again, and at 10.15 he quietly died.

The case is interesting for the following reasons: The family history is good. The child's previous

health was perfect, except for the frequent attacks of tonsillitis.

The diagnosis was complicated, at first, by the doubt as to the part played in the causation of the disease by the blows on the head and the subsequent excitement. The duration of the state of unconsciousness — twenty days — was remarkable, though not unprecedented. Lastly, the enemata were almost all retained, the bowels moved, and the urine passed regularly, throughout the disease.

The temperature was taken by the rectum, but, on comparison, was found to vary but slightly from that taken in the axilla.

The autopsy was made, eighteen hours after death, by Dr. W. W. Gannett.

Body medium sized (for age); well developed; much emaciated; slight lividity of dependent portions; rigor mortis present.

Nothing unusual observed about the calvaria or dura; the sinuses of the latter contained partly coagulated blood.

The pia of the convexities of the brain very dry; the vessels minutely injected. The convolutions flattened, the sulci obliterated. The pia of the base along the chiasma and in the fissures of Sylvius was thickened, and opaque yellowish-gray from the presence of fibrino-purulent material in its meshes. In the above situations, also on the under surface of the frontal and temporal lobes, also on the pons and inner borders of the occipital lobes, were to be seen very numerous gray, translucent nodules the size of a pin's head. The lateral ventricles contained each about fifty cc. of a slightly opaque fluid. The ependyma thickened, grayish, and opaque. The choroid plexuses and velum interpositum markedly injected. In the latter were to be seen several small nodules similar to those described in connection with the pia of the base.

Section of the hemispheres showed nothing remarkable, the puncta cruenta being of about the usual size and number.

The basal ganglia, pons, medulla, and cerebellum also showed no appearances worthy of special note.

The heart of the usual size, and so far as its valves, cavities, and muscular substance were concerned showed nothing unusual.

The pleural surfaces on both sides free from adhesions; the pleural cavities contained no fluid.

Both lungs retracted; everywhere crepitant except at apices, where small nodules could be felt within the lung.

On section, at the top of the left lung, was an opaque, grayish-yellow, cheesy nodule, the size of a pea, surrounded by a narrow border of gray and translucent tissue. At the top of the right lung were several closely aggregated nodules of a similar appearance, forming, together, a mass the size of a small walnut. Otherwise the lungs showed nothing remarkable.

The bronchial lymph-glands were enlarged to the size of filberts, showing, on section, a yellowish, opaque, crumbling material.

The spleen was of the usual size, color, and density. On section, follicles and trabeculae fairly distinct, pulp firm, pale-red in color. Two or three gray, translucent, sharply defined, slightly projecting nodules, the size of the prick of a pin were to be seen.

Kidneys not remarkable.

In the lower third of the ileum were several losses of substance of the mucous membrane; the edges elevated, the bases granular.

Liver showed nothing unusual.

**Diagnosis.** — Tubercular meningitis; acute hydrocephalus; ependymitis; tuberculous of velum interpositum; tubercular nodules in the lungs; tuberculous of bronchial lymph-glands; tuberculous of the spleen; tubercular ulceration of the intestines.

## REPORT ON SURGERY.

BY A. T. CABOT, A.M., M.D.

### GUNSHOT WOUNDS OF THE ABDOMEN.

CONSIDERABLE experience has been gained in the past six months in the matter of the treatment of these injuries.

Dr. William T. Bull reports<sup>1</sup> a case of gunshot wound of the intestines treated successfully by laparotomy with suture of the intestines.

The patient, a man of twenty-two, received a pistol-shot wound entering the abdomen below and a little to the left of the umbilicus.

There was no immediate collapse. Twelve hours after the injury his pulse was 102, his temperature was 100.2° F., and his respiration 30. At this time he had severe abdominal pain in spite of having received about three fourths of a grain of morphia subcutaneously. The abdomen was normal in appearance, and palpation revealed nothing except the existence of universal tenderness. He vomited a little watery fluid and the urine which was drawn contained no blood.

Five hours later (seventeen hours after the wound) his condition was still the same, and Dr. Bull performed laparotomy under strict antiseptic precautions.

When the peritoneum was opened, at least two pints of bloody serum containing little clots but no fecal matter flowed out.

The intestines were congested and were here and

<sup>1</sup> Philadelphia Medical News, February 14, 1885.

there coated with flakes of fibrin, which could only be removed by vigorous rubbing with a sponge.

Loop by loop the intestines were drawn out and inspected, and seven bullet-holes were found and closed by Lembert's suture. Six of the wounds were in the small intestine, and the seventh, in which the bullet was lying, was in the sigmoid flexure.

All of these openings were found plugged by the everted mucous membrane and the intestinal contents did not seem to be issuing from any of them, but when their edges were separated yellow, liquid, fecal matter escaped.

The pelvic cavity was finally sponged out with a two and a half per cent. solution of carbolic acid and the intestinal wounds were rubbed with iodoform. The abdominal wound was closed in the sutures, which included the peritoneum, and was dressed with iodoform and borated cotton.

The operation lasted two hours and was somewhat embarrassed by the fact that the patient did not bear either well.

The patient's after-history resembles that of a difficult ovariectomy, with considerable pain and vomiting, but with steady convalescence.

Dr. Bull narrates, in connection with his report, the history of Kocher's case of pistol wound of the anterior stomach wall, in which laparotomy with suture of the wound was followed by recovery.

In connection with Dr. Bull's case the following report<sup>2</sup> by Mr. Alfred Smith is of interest:—

The patient, a vigorous man, received a pistol wound in the abdomen two and a half inches below the umbilicus. Immediately after receiving the wound he ran half a mile after his assailant, and then walked two miles to where he could receive assistance. From this time he suffered from severe abdominal pain, with steadily failing strength, and died three days after the injury. An autopsy revealed general peritonitis. The small intestine was uninjured. In the anterior wall of the descending colon, eighteen (?) inches from the rectum, was a wound one fourth of an inch in diameter, plugged by a piece of clothing. Three inches lower down in the posterior wall was a corresponding wound with much extravasation.

In regard to proper treatment of the wounded intestine Dr. Byrd, in a recent paper,<sup>3</sup> advocates the establishment of an artificial anus, which can be subsequently closed by operation if desired. He considers that there is great danger of sloughing about a gunshot wound, even in tissues which at the time seemed intact. The establishment of an artificial opening also, he says, gives the gases which form in the intestine a chance to escape, thus relieving dangerous pressure on the thoracic organs and avoiding the tension that might tear out the stitches had the wound been sewed up.

To support his view he quotes from Treves, who is also a strong advocate for an artificial anus when a portion of intestine is removed, except when the opening is in the jejunum high up.

#### OPERATIVE TREATMENT OF SPINA BIFIDA.

At a meeting of the Clinical Society of London held March 27, 1885, Mr. Mayo Robson de-

scribed four cases of spina bifida in which he operated by removing the sac under antiseptic precautions.

They were briefly as follows:—

(1) A child, six days old at the time of operation, lived a year and then died in teething (?) convulsions. At the time of death the site of the tumor presented only a linear scar.

(2) A girl eighteen days old and very puny survived the operation but a short time. As the wound healed by first intention and there was at autopsy no sign of meningitis, the death did not seem to be the result of interference.

(3) A girl sixteen years old had a spina bifida in the lumbar region as large as a fetal head. After several aspirations the sac suppurated. It was accordingly removed and the child, who recovered, was shown to the Society.

(4) A child of seven had a lumbar spina bifida seven and one-half inches in circumference. The sac was thin and inflamed. The patient, however, made a good recovery, being entirely well in thirteen days, and was shown to the Society six weeks later with a linear scar to mark the site of the tumor.

Mr. Robson called attention to the importance in these operations of bringing together the serous surfaces of the meninges just as peritoneal surfaces are brought together in abdominal surgery. The lines of suture of the skin and of the meninges should not come opposite each other. When the coverings are thin and the opening into the spinal canal large a flap of skin should be turned in over the opening by a plastic operation.

CASE III. was a most notable success of the antiseptic method in these cases. The sac was already acutely inflamed, when its complete removal and efficient drainage effected a cure. Mr. Robson considers that these cases ought to be let alone: (a) When the deformity is very extensive, as in fissure of the whole or a considerable portion of the vertebral canal. (b) When there is complete paraplegia. (c) When the sac is large, the fissure extensive, and the coverings thin quite to the edge of the tumor with not enough skin in the neighborhood to cover the defect. On the other hand, he thinks that the operation ought to be done (a) when the sac communicates with the spinal canal by only a narrow neck which can be closed by a single ligature; (b) when the sac has a good skin cover even if the opening is large. In this case human periosteum may be placed beneath the skin with a hope of forming a plate of bone; or possibly the vertebral arches might be sprung together and held by fine silver wire.

When the spinal cord or nerves are found blended with the sac, which often cannot be told until the dissection of the skin from the meninges is made, he would advise excision of fractions of the redundant sac at one or more places between the nerves, replacing the nervous structures in the spinal canal, and bringing over the skin cover with free drainage between the skin and meninges. Or if this could not be done, the membranes might be punctured, the collapsed sac with the nerves intact being placed in the canal with a skin cover as before.

## POISONING FROM CORROSIVE SUBLIMATE IN SURGERY.

Fränkel<sup>4</sup> reports fourteen cases of death during the employment of corrosive sublimate on wounded surfaces.

In twelve of these cases he regarded the poisonous action of the drug as but one factor in the production of the fatal issue; all of them being cases of serious injury or disease. In the remaining two, however, he considered death directly caused by the corrosive sublimate. The prominent symptom in all of these cases was a bloody diarrhoea, while salivation was not noticed in any of them.

Post-mortem examinations showed in every instance an inflammation of the intestine, most noticeable in the larger intestine and accompanied by sloughing ulcerations of the mucous membrane.

All the patients were feeble, and either emaciated or abnormally fat.

Dr. George L. Peabody<sup>5</sup> was induced by the above report of Professor Fränkel to investigate the records of the New York Hospital for the past eighteen months.

Eleven cases were found in which the use of this drug as an antiseptic application to wounds was followed by diarrhoea which did not yield to the usual remedies, and which sometimes ceased on the sublimate being discontinued, but which in seven cases became bloody in character, was accompanied by griping pains, tenesmus, prostration, and death.

In three of these seven cases autopsies were made, and in all of them a very extensive diphtheritic inflammation of the larger intestine was found.

The solution of corrosive sublimate used in these cases was usually 1 to 2000, and the wound surface was ordinarily large.

Schede<sup>6</sup> in a recent paper admits the dangers of the sublimate in certain conditions but thinks it doubtful whether the intestinal lesions ascribed to it may not sometimes be pyæmic. Fränkel, however, carefully differentiated his cases from pyæmia, and in Dr. Peabody's patients the other lesions usual in pyæmia were absent.

Dr. Peabody concludes by saying that it is proper to state that, so far as he can learn, death or serious poisoning has not resulted from its use in dressing materials but only after its employment in the irrigation of large wound surfaces.

## LIGATURE OF ARTERIES FOR ANEURISM.

Mr. T. Holmes<sup>7</sup> discusses at some length the question of double distal ligature in aneurisms of the innominate artery and arch of the aorta.

He thinks it a mistake to tie both the carotid and subclavian at one operation, and advises that the carotid alone be first operated. As the carotid has no branches in the lower part of its course a clot is more likely to form and extend back out of it into the aneurismal sac than would be the case after ligature of the subclavian, which has large branches close to its origin, through which a vigorous collateral circulation is carried on. The greater ease with which the carotid can be reached is an additional reason for its selection for the primary ligature.

He says: "The only reason that has ever been advanced for performing the two ligatures simulta-

neously (in ordinary cases when compression of the subclavian gives negative results) is that there may be some inconvenience in administering an anæsthetic twice, and some additional mental disturbance in submitting to two operations. But surely this is somewhat fanciful, . . . and the experience of the double-distal deligation proves that there is no inconvenience in thus dividing the treatment into two stages, even if we were quite sure that the second stage would be called for, which is far from being the case. . . . In fact, if there were no other successful case on record except Evans's, that case would of itself suffice to show that the ligature of the right carotid only may suffice, for the man was restored to complete health, and lived to an age beyond the ordinary term of existence an active and, indeed, an imprudent life. . . . This case, then, in which only the carotid was tied is the most successful instance of the distal ligature on record."

Mr. Holmes concludes his interesting article by saying, "One thing has been abundantly proved by the tolerably long series of operations now on record for thoracic aneurisms, that far more success has been attained by the distal ligature than by electrolysis or by any other form of treatment. And good reason has been shown for preferring the isolated ligature of the carotid artery as the first step in the treatment unless there be some definite indication for tying the subclavian at the same time. Such indications would be either the manifest growth of the subclavian portion of the sac or the effect of compression of the subclavian in diminishing the size or pulsation of the tumor."

O. Riegner<sup>8</sup> reports the following remarkable case of ligatures of both carotids:—

"In September, 1881, the left common carotid was tied for an aneurism of that vessel that had come rapidly (six weeks), and the growth of which could not be controlled by any general or local measures. A double ligature of catgut was applied without division of the vessel between.

"The operation was followed by severe cyanosis of the face, which disappeared in a few hours. Pupils remained equal, and there was no paralysis of any kind. The wound healed by first intention, and the dysphagia and hoarseness which had existed before the operation vanished.

"A year and a half later an aneurism developed upon the other carotid. Sufficient pressure to control the circulation in it caused dizziness, loss of vision, and severe cyanosis. Gradually, by keeping the patient on the back, with ice to the tumor and gentle pressure, a condition of tolerance was reached, so that pressure sufficient to control the circulation could be borne for five minutes without brain symptoms. The carotid was now tied with a double ligature as before. Immediately after the operation the pupils were contracted, then widely dilated, then unequal with the right narrower than the left. For twenty minutes there was great cyanosis of the face. Some hours later this disappeared, and the pupils became again equal. Slight delirium, with weakness of left arm developed during the night, but passed off by the morning after the operation, and the recovery from this time was rapid."

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

REPORTED BY H. L. BURRELL, M.D., SECRETARY.

MAY 4, 1885. DR. W. INGALLS in the chair.  
DR. W. CHANNING read a paper on the

#### TEMPERATURE OF THE INSANE.<sup>1</sup>

DR. EDES asked what sort of a temperature the reader would expect to find in insane patients who complained of excessive heat; whether the feeling of heat in these cases was subjective or not.

DR. CHANNING thought that the sensation of heat was subjective, as he had seen illustrative cases.

DR. EDES called attention to the fact that the morning and evening temperature may not give us the highest and lowest temperature of the twenty-four hours. In phthisis, for example, a normal temperature may exist in the morning and at night, but yet at noon a very high temperature may exist. In fact, the maximum temperature may come at any time in the course of the twenty-four hours. A thermometer which would record the variations in temperature for twenty-four hours would be apt to give us new facts regarding the relation of temperature to disease. Dr. Edes thought he remembered having seen the description of such a thermometer, one arranged like an aneroid barometer.

DR. J. J. PUTNAM said that he had been much impressed with the truth of Charcot's statement that the temperature in the rectum in elderly persons was relatively higher than in young adults. He mentioned a case of pneumonia, in an old man, where the temperature by the mouth was 100° F., but in the rectum it was 103° F.

DR. FISHER spoke of the difficulties attending taking temperature in the insane. He considered it a very valuable source of information, and wished that a series of observations might be carried out in some large asylum. He spoke of the temperature of patients having "general paralysis." In the first stage the temperature is high, in the second stage lower, and in the third stage it is high again. He had noticed unusually low temperature in cases where a trance state existed; also in some cases of melancholia. He asked the writer how the wet pack was given.

DR. CHANNING said that he used the wet sheets to envelop the patient. When the temperature fell the sheets were removed. He had been struck by the quietude produced by this treatment.

DR. FISHER mentioned that in English hospitals, where "non-restraint" is the rule, wet packs are used ostensibly to reduce temperatures; he suggested that they were possibly used to restrain patients.

DR. PAGE inquired if the wet packs had induced sleep. At the Adams Nervine Asylum he had frequently seen a wet pack not only quiet the restless motor excitement, but had seen patients fall asleep after its use.

DR. CHANNING, in reply, said that he had never seen sleep produced by a wet pack.

A discussion then ensued on the methods of giving

wet packs, it being the general opinion that the use of blankets over the sheets produced diaphoresis.

DR. INGALLS related a case of scarlet fever in a child six or seven years of age, where there was serious nervous excitement. The use of a wet pack, with blankets, produced diaphoresis and amelioration of the symptoms. Dr. Ingalls wished that the minimum time for accurately taking a temperature could be settled.

DR. EDES thought that the record of a temperature taken five minutes was accurate enough for practical purposes.

DR. DENNY called attention to the differences in the cerebral temperature of the halves of the head. In health the temperature of the right half of the head is higher than the left when the observed is in active conversation. One might infer that in insanity the right half of the head might be as high as the left half. Dr. Denny asked the reader if he thought there was a congestion of the local centres in the medulla oblongata in these cases.

DR. CHANNING considered that there might be.

DR. DENNY suggested that a loaded condition of the rectum frequently accounted for high temperature.

DR. CHANNING closed the discussion. He said that when it would be convenient he should much prefer cold baths to the use of the wet pack.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

MARCH 11, 1885. The PRESIDENT, DR. A. D. SINCLAIR, in the chair.

DR. HENRY P. JACQUES, of Milton, reported, by invitation.

#### A CASE OF TUBERCULAR MENINGITIS: DEATH: AUTOPSY.<sup>1</sup>

DR. W. L. RICHARDSON said that the hygienic surroundings of the patient had always been the best, and the child had been brought up by its parents with every possible care which commonsense, aided by medical advice, could prescribe. With the exception of slight attacks of tonsillitis, the child had never been under medical treatment. There was, however, one fact in the past history of this patient that might have a bearing on the case and he would like to have Dr. Gannett's opinion. When the patient was fourteen months old the services of a nurse were engaged, and that nurse remained in care of the patient until last fall, when he was about four and one-half years old; at that time her health, which had been failing during the latter part of the spring and summer, had become so poor that she was obliged to leave. She had a cough and had lost considerable flesh and strength. She subsequently went to Colorado Springs, where she now is, and her health has considerably improved. A sister at about the same age had died of consumption and another sister had also died, although the cause of her death was unknown.

DR. GANNETT said that one of the most interest-

<sup>1</sup> See p. 1.

<sup>2</sup> See p. 5.

ing and important points in an autopsy upon a case of tubercular meningitis was the determination of the source of infection.

Inasmuch as all cases of tuberculosis of the pia are secondary, one should make a careful search in all parts of the body for evidence of primary tuberculosis, either in the form of cheesy nodules or else of nodules made up of growing tubercles.

In the present case the infecting source was evidently in the lungs; there being cheesy nodules at both apices, as described in the autopsy report, surrounded by a periphery of actively growing tubercles and also cheesy bronchial lymph-glands.

Dr. Gannett thought it quite possible that a child might be infected with tuberculosis by living day and night with a nurse already tubercular.

Dr. WEBER said he was asked to see the patient on the ninth of January. The symptoms were such as to lead to a strong suspicion of tubercular meningitis; but considering the family history and that the child had been perfectly well up to Christmas, also taking into account the falls and consequent injury to the head, it seemed to him the more probable that the disease was simple meningitis. After falls and blows upon the head there is at times a period of latency, during which there are either no symptoms, or they are very slight. Guided by past experience in this respect he was led to state that while tubercular meningitis was possibly present, he thought the chances were in favor of the simple form of the disease. A few days later Dr. Richardson gave him an account of the progress of the symptoms and it was quite evident that it was a case of tubercular meningitis.

He examined the patient with reference to the *taches cérébrales*, but could not obtain them. In a majority of patients, when the finger-nail is drawn across the abdomen, a red line appears after some time, but only slowly and is not very intense. The symptom is of value only when it appears very quickly, within two or three seconds, and is of deep color. The line made with the nail is brighter than when the finger is drawn over the surface. By the side of the red line the skin acquires a pale tint, almost white, as if the smaller vessels were contracted. This sign is of much less value than was formerly supposed.

Dr. C. J. BLAKE said that, so far as the ears were concerned, both membrane tympani were clear, normally transparent, and without injection of the manubrial bloodvessels, the mucous membrane of the tympanic cavities, as visible through the membrane tympani, was also free from injection, and there was, in fact, no evidence of disturbance of the ears.

On the posterior wall of the external auditory canals at the inner third, more pronounced in the right than in the left ear, was a circumscribed patch of injection such as is observable in cases of inflammatory process in the mastoid antrum and occasionally accompanying congestion of the middle ear uncomplicated.

Dr. ROTCH made the following remarks on the case and also discussed the difficulty of making a differential diagnosis and of giving a prognosis in the early days of the disease:—

First, as to the diagnosis of cerebral disease at

all, we must remember that there is a wide difference between the symptoms resulting from exactly the same diseases in the adult and in the child; the former presenting, as a rule, symptoms corresponding to lesions of the organ involved, while the latter, owing to the active development and sensitive condition of its nervous system, is liable, no matter by what disease it is attacked, to have such a profound impression made on its nervous centres, that quite frequently actual disease of these centres is simulated, thus for days masking, by their undue prominence, the symptoms of the especial disease, perhaps of thorax or abdomen, which will finally assume control and declare the diagnosis. As illustrating this point Dr. Rotch spoke of cases which had been lately under his observation: in one there was hemiplegia occurring during an attack of simple reflex eclampsia and passing off within a few hours; in another, a child lay for days in about the same condition of unconsciousness as in the reader's case, as the result of a fall, but no lesion external or internal being discovered throughout this time. Again, there are cases of fibrinous pneumonia, where children lie for days in an unconscious condition and where no lesion can be discovered in the lung, consciousness only returning as the physical signs develop in the lung, and during this period entire uncertainty may exist as to the locality of the disease.

In this connection Dr. Rotch said a few words in reference to his examination of the lungs, which, as reported in the paper, might lead to some misapprehension if left unexplained. The slight change noticed at the apex of the right lung was not at the time considered of any importance, so soon as the possibility of an acute pneumonia developing in that locality was dismissed as untenable, and was not considered as exercising any influence in aid of the diagnosis of the case; in fact, it was supposed to be physiological rather than pathological. Dr. Rotch also spoke regarding the similarity of typhoid during the first four or five days of the disease, the nervous symptoms being so very prominent at this period and closely simulating cerebral disease, as is also the case in certain forms of acute gastric catarrh.

As to the diagnosis of the reader's case, most of the gentlemen who saw the patient concurred in the diagnosis of Drs. Richardson and Jacques, made at the seventh or eighth day, namely, of meningitis, probably of the tubercular form; and, although certain symptoms usually present in a typical case of tubercular meningitis were absent and the general constitutional symptoms of progressive emaciation and altered temper which commonly precede the outbreak of tubercular meningitis at this age were wanting,—the disease being ushered in by cerebral symptoms in a healthy child, a fact which would usually point toward the simple form of meningitis,—yet the general picture of a slowly developing, subacute disease marked by quiescence of symptoms and moderate temperature was very striking when compared with the usually stormy onset and acute development with high temperature of most cases of simple meningitis. Dr. Rotch called attention to a symptom lately spoken of by Koenig, of St. Petersburg, as pointing toward meningitis, though

not necessarily of tubercular origin, namely, contraction of the knee-joints on sitting, with complete relaxation on lying down. An instance of this symptom was at present under his observation in a baby apparently suffering from some obscure cerebral disease.

In answer to a question Dr. Rotch said that he did not consider the *tache cérébrale* to be especially diagnostic of tubercular meningitis. He also said that in the Children's Hospital, at Stockholm, a number of autopsies had been made on infants dying of tubercular meningitis, and, with the exception of two cases, tubercular disease had been found in other parts of the body. These two, however, presented an apparently primary tubercular disease of the cerebral meninges, a careful examination failing to discover any point of infection elsewhere. The difficulty of diagnosis in tubercular meningitis is still further enhanced when we consider that the same well-marked pathological lesions are at times followed by symptoms which do not correspond to those usually occurring and determined by the anatomy of the parts involved; in fact, by a noticeable lack of symptoms.

As to the prognosis of tubercular meningitis, it is probable that every case eventually dies of the disease, but well-authenticated cases have been reported where recovery apparently took place, but later a second attack killed the patient, and the postmortem revealed not only the fresh tubercular lesions, but evidence of tubercle of a former period corresponding to the original attack. Dr. Rotch also stated that the temperature in the reader's case followed the usual rule of uncomplicated tubercular meningitis and was of great aid in the diagnosis, namely, of moderate grade, somewhat variable, and becoming high a day or two before the fatal termination. Dr. Rotch concluded his remarks by drawing attention to the difference between tubercular meningitis occurring during the first six months of life and that of older children. In the former, the prodromal symptoms were, as a rule, absent, a sudden onset like that of a simple meningitis occurring in often apparently perfectly healthy babies; diarrhoea was more common than constipation; sinking of the abdomen was rare; the disease was essentially acute, a fatal issue usually taking place in three or four days.

Dr. WELLINGTON spoke of the case of a child twenty months old who had always been considered healthy until its present illness. The family history was good, except that a niece of the mother had died of consumption. When first seen, three weeks ago, the child was sleepy and had vomited a little; the sleepiness increased and vomiting occurred once in twenty-four hours. At the end of the week there was observed stiffness of one arm; but this disappeared in one day; then there was tonic spasm of the other arm and then of the right leg. Thenceforward drowsiness had increased, the breathing had become irregular, the temperature was elevated one degree, the pulse was slow, but not remarkably so, the bowels were somewhat constipated, the pupils normal; the *taches cérébrales* were well-marked. It was undoubtedly a case of tubercular meningitis. Dr. Wellington inquired if this affection was always secondary.

Dr. GANNETT said that primary cases had never yet been observed.

Dr. LYMAN alluded to the case of a child who lay unconscious for four months, and who was supported by the several able consulting physicians to have tubercular meningitis; yet the child recovered. He emphasized the difficulty of diagnosis between simple and tubercular meningitis, and asked if it was not unusual in the latter disease to have such remissions as apparently occurred in this case.

Dr. ROTCH said it was not uncommon to see remissions even up to a short time before death.

Dr. REYNOLDS said that blows on the head, sometimes of trifling character, occasionally furnish the proximate cause of tubercular meningitis in cases wherein the tubercular diathesis already exists. He was convinced that in families with a tubercular predisposition much good might be effected by timely prophylactic treatment. At the earliest approach of threatening symptoms active hygienic and medicinal means should be employed. He quoted Lewis Smith as advocating the use of the iodide and bromide of potassium in small repeated doses as of great prophylactic value.

#### SPECIMEN OF A NORMAL UTERUS AT THE END OF THE SIXTH MONTH OF PREGNANCY.

Dr. GANNETT exhibited, by invitation, a uterus and its appendages coming from a woman six months pregnant, who had died about ten hours after delivery; the patient having been, for several days, in a dying condition from extensive softening of the brain.

The specimen was of interest as showing the normal appearances presented by a uterus shortly after delivery at the sixth month.

The cervical canal had not become obliterated; on the contrary, it was about three centimetres long. There was a well-developed corpus luteum in the left ovary.

The body of the uterus measured vertically sixteen centimetres, transversely eleven centimetres, antero-posteriorly seven centimetres. Its walls measured on an average 2.2 cm.

#### FŒTUS PAPYRACEUS.

Dr. W. L. RICHARDSON showed a specimen which had been sent to him by Dr. R. A. Kingman. The woman had been delivered at full term. An examination of the placenta showed a second placenta which had undergone complete fatty degeneration, and in the membranes attached to it was a flattened fetus, the growth of which had been arrested during the fourth month, as shown by its length and the ossification of the bones. Dr. Richardson said he had seen a similar case at the Boston Lying-in Hospital, in which with triplets one of the children had died at the third month. The pregnancy had gone on uninterruptedly and the labor was normal.

Dr. KINGMAN, present by invitation, said: The patient from whom the specimen came is a primipara, twenty-seven years old, a large, stout, healthy woman. With the exception of moderate nausea and vomiting extending over nearly the whole period of pregnancy, she has had no illness since conception. After a normal labor, a healthy female child of six

pounds in weight was born alive and has maintained a vigorous existence since that time.

The pregnancy was supposed to have dated from the later part of April, 1884, at which time the last menstrual period ceased, but the labor did not occur until March 8, 1885. No difficulty was experienced in expressing the placenta, the membranes following readily a few minutes later.

#### TREATMENT OF THE NAUSEA AND VOMITING OF PREGNANCY.

DR. ABBOT said that he had known marked relief to follow the exhibition of small doses of ipecacuanha, when all other remedies had failed.

DR. RICHARDSON had found ipecacuanha very efficacious in doses of two drops every two hours. He suggested that hydrochlorate of cocaine in capsules might prove successful in such cases.

DR. H. W. WILLIAMS said that from his experience with the anæsthetic properties of cocaine in ophthalmology, he should think this drug would be very efficacious in the nausea and vomiting of pregnancy.

DR. WEBER alluded to a case, seen many years ago, in which the patient had been brought very low by extreme nausea and vomiting which had resisted all remedies: relief was obtained, however, by the use of oxalate of cerium in two-grain doses repeated every hour or two.

DR. LYMAN said that the topical application of iodine, to be effective, should be made within the cervix, not simply around the os externum.

DR. BOARDMAN had used with good results small, frequently repeated doses of calomel—one twentieth to one tenth of a grain every hour.

DR. INGALLS had found one-eighth-grain doses of opium, repeated every hour, efficacious in relieving nausea.

DR. BAKER said he had been called in two cases to produce abortion on account of obstinate and alarming vomiting: he found the uterus in marked anteversion in both cases, and by the application of a suitable pessary to raise the womb both patients were relieved.

#### RHODE ISLAND MEDICAL SOCIETY.

THE Seventy-fourth Annual Meeting of the Rhode Island Medical Society was held in Lyceum Hall, Providence, June 11, 1885, Vice-president HORACE G. MILLER, M.D., in the chair.

The Secretary's annual report showed fourteen additions to the list of Fellows during the past year, three removals from the State, and no deaths. The present active membership is one hundred and ninety-eight.

DR. C. H. LEONARD, Treasurer, read his annual report. Total receipts, \$869.38; outgo, \$721.70; balance on hand, \$117.68. The printing fund increased during the year to \$1,912.47.

DR. C. W. PARSONS, Secretary of the Trustees of the Fiske fund announced that a premium of two hundred dollars had been awarded to Charles V. Clapin, M.D., of Providence, for the best essay on "The Present State of the Germ Theory of Disease." A premium of two hundred dollars had also been awarded to Hobart Amory Hare, M.D.,

of Philadelphia, for the best essay on "The Physiological and Pathological Effects of the use of Tobacco." The trustees regret that under the provisions of the will they are unable to award a second premium for an able essay on "The Use of Tobacco."

The trustees propose the following subjects for 1886:—

I. "The Methods and Practical Results of Treatment of the Malarial Diseases now Prevalent in New England."

II. "New and Altered Forms of Disease Due to the Advance of Civilization in the Past Half-Century."

For the best dissertation on either subject worthy of a premium they offer a prize of two hundred dollars.

DR. G. W. PORTER presented the report of the Publishing Committee, and the Committee received a vote of thanks for its efforts.

DR. T. NEWELL, Chairman, read the sixth annual report of the Committee on the Library: 1,007 volumes were added during the year; the total number of bound volumes at present in the library is 4,593.

DR. W. J. McCRAW, Chairman, presented the first annual report of the Committee on the Museum. The circular issued by the Committee had met a generous response. Nearly one hundred valuable anatomical or pathological specimens had been received from Fellows of the Society and as many more, on deposit, from the Providence Franklin Society.

DR. S. S. KEENE, on behalf of the Board of Censors, stated that Drs. Gilbert L. Church, of Warren, James B. Erskine, of Johnston, Sophronia A. Tomlinson and Vernon O. Taylor, of Providence, having passed satisfactory examinations were recommended for fellowship. They were elected unanimously.

DR. ARIEL BALLON reported as delegate to the New Orleans meeting of the American Medical Association.

DR. W. H. PALMER reported verbally as a delegate to the Connecticut Medical Society.

The President introduced to the Society Drs. W. H. Carmalt and J. B. Kent, representing the Connecticut Medical Society, and J. R. Bronson, of Attleboro', a delegate from the Massachusetts Medical Society. Dr. Bronson made an earnest plea for State laws regulating the practice of medicine.

Officers for 1885-86 were elected as follows:—

Oliver C. Wiggan, President; Horace G. Miller, First Vice-president; John W. Sawyer, Second Vice-president; George D. Hersey, Recording Secretary; Edward M. Harris, Corresponding Secretary; Charles H. Leonard, Treasurer.

Censors: Drs. Ariel Ballou, J. H. Eklredge, J. W. C. Ely, G. P. Baker, S. S. Keene, Benjamin Greene, Eugene Kingman, Job Kenyon.

The Standing Committees of last year were re-elected, with a single exception, Dr. F. H. Peckham, Jr., being chosen Auditing Committee.

DR. E. T. CASWELL called attention to the commendable work which some of the younger members of the Society were doing in gathering and preserv-

ing pathological specimens which would otherwise perish and at his suggestion the Society voted one hundred dollars for the use of the Committee on the Museum.

A communication from the American Medical Association relative to establishing a State Board of Medical Licensers was referred to a committee of three to be appointed by the President.

On account of the illness of the President, the delivery of the annual address was postponed to some subsequent meeting.

Following adjournment, one hundred and twenty-five Fellows with invited guests sat down to the annual dinner which was served in Blackstone Hall, Dr. Eugene Kingman presiding as Anniversary Chairman. After-dinner speeches were made by Dr. J. R. Bronson, Mr. C. H. George, Mr. John Huntsman, Drs. Caswell, Browning, Burge, Kent, and Arnold, and by Rev. Dr. J. G. Vose.

#### AMERICAN NEUROLOGICAL ASSOCIATION.

ELEVENTH Annual Meeting, held in the hall of the Academy of Medicine, New York, June 17, 18, and 19, 1885.

##### FIRST DAY'S PROCEEDINGS.

The Association was called to order by the retiring President, DR. ISAAC OTT, of Pennsylvania, who briefly referred to the subject of the temperature centre, to which he had been devoting special study. He thought it could now be said that the temperature of the body was as much under the control of the nervous system as was the action of the heart. His own investigations, and those of some other observers, pointed to the anterior portion of the optic thalami as the seat of such centre. Dr. Ott then introduced the Vice-president.

DR. LEONARD WEBER, of New York, then took the chair.

The report of the Secretary and Treasurer, DR. GEORGE M. HAMMOND, showed a balance in the treasury of \$38.50.

##### NOMINATION OF OFFICERS.

For President, Dr. C. K. Mills, of Philadelphia; for Vice-president, Dr. V. P. Gibney, of New York; for Secretary and Treasurer, Dr. R. W. Amidon, of New York; for Council, Dr. Geo. W. Jacoby and Dr. E. C. Seguin, of New York. As there was but one nomination for each vacancy, the Secretary was instructed to cast an affirmative ballot for those nominated.

The amendment to the by-laws to have the meetings held on the first Wednesday in May instead of on the third Wednesday in June gave rise to discussion, but was not acted upon. The amendment calling for the transaction of all business not of a scientific nature in executive session, to be held after each scientific session, was passed.

##### A CASE OF CHRONIC MYELITIS: RECOVERY.

DR. A. D. ROCKWELL related the history of a girl sixteen years of age who, on the twenty-second of September, 1881, was referred to him by Dr.

Farrington. Three months before she had sat on a cold rock, at a picnic, and on returning found she walked with difficulty, and within a week the lower limbs became completely paralyzed, and also the sphincters of the rectum and the bladder. The patient was extremely nervous and sleepless. A large bed sore formed which was very intractable to treatment. When Dr. Rockwell saw the patient, the electro-muscular irritability was entirely abolished to both currents, the legs were contracted beyond the power of forcible extension, the sphincters paralyzed, the bed sore showed a tendency to increase. The limbs, although sensitive to touch, showed diminished sensibility when tested with the aesthesiometer. The prognosis was considered very unpromising, but at the urgent request of the father treatment was continued, the galvanic current being substituted for the Faradic, applications being made to the legs and lower portion of the spine. At the end of the fourth week of treatment very faint muscular contractions were observed, which later showed that they were the reactions of degeneration. At the end of four months he discharged the patient as cured, except for slight weakness of the flexors of the right leg.

DR. ROCKWELL thought that in this case the tendency was either to degenerative softening or atrophy of the ganglion cells; he thought the latter. That the whole transverse area of the cord was involved, he thought, was shown by the complete abolition of both afferent and efferent nerve function.

DR. E. C. SEGUIN said the case was an interesting one, and reminded him of several which he had seen of typical subacute polio-myelitis, the diagnosis being obscured by the weakness of the sphincters and slight dullness of sensibility. He believed that was all there was in this case; there was not absolute anaesthesia. He thought this case would come into the category of somewhat modified polio-myelitis, with some extension into the gray matter. It certainly could not be brought forward as an example of cure of myelitis transversa. It left our unfavorable prognosis of that disease unchanged. He referred to a case of apparent diffuse myelitis of the cord, principally of the anterior horns, seen with Dr. Delafield, the patient having completely recovered within three years. Dr. Rockwell's case was particularly interesting with regard to treatment; while there had been time for spontaneous recovery, he had no doubt that galvanism had been of great service in expediting the cure.

DR. ROCKWELL remarked that in this case there was complete paralysis of both the bladder and rectum. He had seen a number of cases of recovery from polio-myelitis anterior.

DR. GRAY, of Brooklyn, said it depended upon what was regarded as evidence of chronic myelitis as to whether or not a cure could be effected. After all, we knew very little about myelitis. We could diagnose a myelitis of the anterior horns, and of the columns of Burdach or locomotor ataxia, and we could diagnose myelitis of the lateral pyramidal columns. But experimental and pathological observations went to show that there were many other columns in the cord which were functionally distinct from one another. Then with

regard to what was considered a chronic case, perhaps opinions would differ. According to his observation, recovery of chronic cases was not so rare as Dr. Rockwell seemed to think. He mentioned an instance of paralysis of the lower limbs in which over a year elapsed before recovery was established. Sometimes cases were quiescent for a period, and suddenly improvement would follow the use of electricity after failure of other agents.

#### METHODS OF STAINING IN MICROSCOPICAL WORK.

DR. ALLEN M. STARR, the author of the paper, described the following methods of staining, pointing out their comparative value, and presented microscopical slides illustrative of each: The hæmatoxylin method; the acid-fuchsin method; Dr. Seguin's modification of the anilin-blue method; Sahlis's double stain with methyl blue and acid fuchsin; and, lastly, the saffranin stain. Each method had its special advantages, but on the whole the first two named were the best; they were superior in all respects to the older carmine method.

#### ON THE USE OF OSMIC ACID IN PERIPHERAL NEURALGIAS.

DR. GEO. W. JACOBY, of New York, read a paper on this subject, first reviewing the observations of Neuber, Eulenberg, etc. In all, about fifty cases of peripheral neuralgias had been treated by this method by different writers. Eulenberg had obtained very good results, there being out of twelve cases three cured, four benefited, five inactivated. Other cases so treated had given even better results. Dr. Jacoby used one per cent. solution of osmic acid in water; of this, half a gram to a gram was injected. The acid should be dispensed only in a dark bottle and a small quantity prescribed at a time. It caused a smarting, burning sensation when injected hypodermically, the pain generally subsiding after a few seconds. No constitutional symptoms were produced. There was sometimes fullness over the seat of puncture. If various branch nerves were affected it was necessary to make an injection over each branch, but the results were more likely to be beneficial if only a single branch were affected. Of a series of eighteen cases of peripheral neuralgias so treated, Dr. Jacoby gave the details of three. Of the eighteen cases, eight were cured and some others benefited. Sciatica seemed to present the better chance of recovery by this method, and the older cases seemed more amenable to treatment than the more recent, an observation opposed to that of a German physician. In one case hypodermic injection over the radial nerve caused pain to extend down the arm, and paralysis was present the next morning. It was true the patient had slept on the arm during the night, but Dr. Jacoby was inclined to attribute the paralysis to the injection of osmic acid, for French observers had noticed paralysis following injections of ether on several occasions.

The conclusions drawn were: That in osmic acid we had a remedy which was of service in certain cases of peripheral neuralgia; its action localized was frequently beneficial; its use was not altogether free from danger; it was dangerous to implicate a motor nerve during the injection.

DR. SACHS, by invitation, said his experience with osmic acid in peripheral neuralgias had been only partially satisfactory. He had witnessed the treatment at the hands of Eulenberg, and believed that in about one third of the cases no benefit whatever was observed. In some a cure was effected after failure by electricity and various other remedies. One point which he observed at Eulenberg's clinic was that the injection caused no pain whatever, but Dr. Sachs's experience with the drug obtained in this country had been quite different, for it always caused severe pain, and was liable even to give rise to abscess.

DR. E. C. SEGUIN had not used osmic acid in the manner indicated, but he had had some experience with this general plan of treatment. He mentioned some cases in which treatment by injections of nitrate of silver or other agents had been more or less successful, and he was disposed to attribute the result to counter-irritation; perhaps by the production of an abscess. He had also caused paralysis of sensation of the upper lip by injections of chloroform for trigeminal neuralgia, and the same accident had occurred at the hands of a friend. He knew of no case in which motor paralysis had occurred.

DR. JACOBY, in closing the discussion, said he was not quite ready to accept the explanation of the benefit derived on the ground that it was a counter-irritant. Perhaps the fact that the nerve tissue being changed in color in the living subject, as well as in the post-mortem subject, by injections of osmic acid, would point to some other mode of action.

#### SECOND DAY. — AFTERNOON SESSION.

The President, BURT G. WILDER, M.D., in the chair.

#### REPORT OF TWO CASES OF SPIXA BIFIDA CURED;

##### ONE FOLLOWED BY HYDROCEPHALUS.

DR. V. P. GIBNEY read the history of these two cases, which were reported briefly in the proceedings of the New York Pathological Society, winter of 1885. In the second case, a child, the spinal tumor was injected with the iodo-glycerin fluid, and the tumor was thus caused to entirely disappear. After the cure the child died, it was said of cholera infantum, and no post-mortem examination could be made.

#### ON THE USE OF STRYCHNINE IN NERVOUS DISEASES.

DR. GRAY, of Brooklyn, read a paper with this title, and said a paper read by Dr. Jewell, of Chicago, on "The Use of Large Doses of Strychnine in Certain Nervous Diseases," had prompted him to make observations in this direction. He had prescribed strychnine in many cases of myelitis, but only in two truly acute cases in which the drug was not well borne. In one case of transverse myelitis the dose was increased from one fifth of a grain up to one twenty-fifth of a grain, and after four days, without warning, alarming symptoms of strychnine-poisoning developed, and it was difficult to save the patient's life. In one other case also alarming toxic symptoms developed after giving about an equal amount. In five cases of progressive muscular atrophy the strychnine acted as a

stimulant. But no real improvement took place. The drug seemed to be of benefit in certain chronic cases, but he would never risk giving it in larger doses than one twentieth of a grain.

Dr. C. L. DANA had had experience with large doses of strychnia in certain functional forms of nervous disease. One patient who had become unable to attend to business because of mental and physical depression began taking one-fifteenth-grain doses, and increased the amount so that he took in divided doses as much as a grain a day, with marked benefit.

Dr. SEGUN had heard the same ideas regarding the use of strychnia advanced this afternoon also advanced many years ago by Brown-Séquard. Dr. Seguin had given the drug in increasing doses in a number of cases of functional disease of the nervous system with benefit. With reference to Dr. Jewell's practice, he thought it was pretty risky because of the uncertainty of diagnosis in many cases. It had occurred to him that perhaps one reason why Dr. Jewell's cases had borne such large doses of strychnia without evil results was that there was left no central motor apparatus to respond to its influence. Dr. Seguin would recommend the administration of strychnia hypodermically; thus avoiding the explosive effects which might come from a collection of pills in the alimentary tract.

#### PARONYMY VERSUS HETERONYMY AS NEURONYMIC PRINCIPLES.

The President, Dr. B. G. WILDER, of Ithaca, New York, read an address with this title. The desirability of a change of encephalic nomenclature was shown by quotations from various authors. The object was to insure greater accuracy and brevity, and to facilitate the means of communicating knowledge between neurologists of all nations. It was proposed to discard vernacular names, to make a selection of shorter technical classical ones, to abbreviate some by omission of unessential words and others by the substitution of prefixes for adjectives. The numbers of terms used in the principal languages to designate different parts of the brain is about nine thousand, whereas somewhat more than five hundred were sufficient. Dr. Wilder disclaimed having any desire to coin new words; on the contrary, he had lain awake more nights in thinking of how to avoid the necessity for this than in any other study. After giving the subject much attention he had concluded that neurity would be most advanced by the employment of technical Latin names as far as possible with an English dress or with a vernacular face and aspect. What he proposed and advocated was simply this: that so far as possible for each part of the neuron or central nervous system there should be found or made a name consisting of a single Latin word; that for each such Latin name there likewise be found or made an English equivalent, not a translation, but a paronym; and, further, that in obtaining these names, Latin and English, due regard be had both to existing nomenclature and the established rules of etymological conversion. He hoped it would now be understood that he did not wish, much less undertake, to upset names as they then existed. Most of the words

which he had proposed were old terms translated, combined, or abridged. By the use of paronyms instead of heteronyms any neurologist would recognize the name of any portion of the neuron when seen in Latin, Italian, Spanish, French, English, or German.

#### THE RELATION BETWEEN THE SYMPTOMS AND THE LESIONS OF POSTERIOR SPINAL SCLEROSIS.

Dr. E. C. SPITZKA read a paper with this title, in which he gave an analytical review of cases reported by different authors, and also the observations which he made in two cases in which an autopsy had been obtained. The following were his concluding remarks: While it must be admitted that the primary lesion of tabes is competent for each affected level of the root zones and great horns to produce all the characteristic symptoms of tabes referable to that level, yet, in the extent and distribution of the consecutive lesions, we have valuable guides to the extent, severity, and duration of the primary disturbance; and we may attribute to the following special disturbances the ensuing degeneration of the tracts whose functions are abolished or diminished:—

(1) That of the column of Goll to the disturbance of muscular sense in the lower extremities; (2) that of the comma-shaped internal bands of the column of Burdach to the corresponding disturbances in the upper extremities; (3) that of the triangular area bordering on the periphery of the cord and its posterior root entry to the rarer analgesic development; (4) that of the column of Clark and direct cerebellar tract to the disturbed space sense. It was probable that some of these views would in time have to be modified.

Dr. SEGUN called attention to the insusceptibility of tabetic patients to the sensory influences of acouitina.

He had observed that in both the first and second stages of tabes it required very large doses of acouitina to produce the peripheral subjective sensations so characteristic of the action of that drug upon the spinal axis in healthy subjects. Perhaps, out of fifteen cases of tabes only one patient manifested the tingling sensations in the extremities usually seen, and in that patient it required enormous doses. The amount taken by two or three patients was almost sufficient to produce collapse; but they had not the special symptoms referred to. It had occurred to him that perhaps this fact was to be explained by an early change in the part of the gray matter in the cord referred to by the author. He thought it was opposed to the view that acouitina acted on the peripheral extremity of the nerves.

#### ON A SELDOM-DESCRIBED ARTERY: ARTERIA TERMATICA; WITH SUGGESTIONS AS TO THE NAMES OF THE PRINCIPAL ENCEPHALIC ARTERIES.

THE PRESIDENT demonstrated the arteria termatica, which he had always found given off from the anterior communicating, or, in case of the absence (which was frequent) of the anterior communicating, from the juncture of the two anterior cerebral arteries. The interesting feature of the artery was that it was azygos. He proposed to name the principal encephalic arteries in accordance with the

principles of neonymy laid down in his address. For example, instead of anterior communicating he would say precommunicant, and instead of posterior communicating, postcommunicant, etc.

Dr. STARR had observed absence of the precommunicant artery in two brains out of fifteen dissected during the past winter.

#### ON TWO LITTLE-KNOWN CEREBRAL FISSURES, WITH SUGGESTIONS AS TO FISSURAL AND GYRAL NAMES.

The President showed in the human brain the fissura inflecta, described only by Italian writers; also a fissure near the olfactory bulb, most distinct in animals, called by Owen the basirrhinal fissure. Dr. Wilder had arrived at the conclusion that this fissure was of important morphological significance, and had found on farther reading that his views in this respect were only confirmatory of Owen's and Broca's. For fissural and gyral names he would use single words with prefixes, pre-, post-, sub-, etc.

#### TWO CASES OF FRIEDREICH'S DISEASE.

The paper was written by Dr. WILKINSON SINKLER, of Philadelphia, and in his absence was read by Dr. MASSEY. The two cases described were almost typical cases of Friedreich's disease, with the exception that they were not hereditary. There was no history of syphilis. No autopsy was made.

Dr. SEGUN had recently published five cases of Friedreich's disease, and he also briefly referred to some cases by Dr. Smith, of Boston.

Dr. AMIDON had under observation two cases of what he believed to be Friedreich's disease, the symptoms in one of which he briefly described. The paper was also discussed by Dr. STARR and Dr. JACOBY.

#### A GALVANOMETER.

Dr. GEORGE W. JACOBY presented a galvanometer, the invention of Dr. Budisch. The relative value of this and other like instruments was discussed at considerable length.

#### A BRAIN MONSTROSITY

was presented by Dr. SPITZKA at the evening session. The specimen was removed from the body of a child aged two and a half years, who had a number of deformities of the extremities. The chief interest in the malformation in the brain was cerebellar. Dr. Spitzka also presented specimens illustrating Gudden's atrophy method, which had a bearing on the anatomy and physiology of the tracts comprised under the name *kerniscus* or fillet, and also on the anatomy of the trineural fasciculus.

The President then exhibited specimens illustrating (1) the form and extent of the adult aulla; (2) the non-extension of the rima to the tip of the mediotrunc; (3) the enlargement, yet complete circumscription, of the porta in an alinjected hydronephal; (4) the fibrial revert and its relations to the prosoplex; (5) the continuity of the diacoidal encloma from the mesal surface of the thalamus over the habena to the diatele; (6) the insula in a dog, monkey, chimpanzee, and porpoise.

#### A CONTRIBUTION TO THE PATHOLOGY OF THE CEREBELLUM.

Dr. E. C. SEGUN read a paper with this title, and related the history of a case of a man, a soldier, whose first symptoms developed about 1857,

and ten years later it appeared he had epileptiform or epileptoid attacks, headache, typical cerebellar incoördination, no distinct paralysis or ataxia, nystagmus, increased patella reflex. These symptoms remained nearly stationary during the unusual long time from 1871 until a short time before death, 1885. Dr. Seguin made a diagnosis of disease, probably a tumor, of the superior cerebellar vermis. There was no history of syphilis. The autopsy showed extensive atheroma of the cerebral arteries in patches, yellow in color, and of the type considered significant of syphilis, but this disease, he thought, could be excluded. There was a very considerable cyst of the superior vermis, extending at least an inch into the right hemisphere of the cerebellum, and probably pressing upon the floor of the fourth ventricle.

Dr. BAUDUY, of St. Louis, then read some

#### NOTES ON HYDROCHLORATE OF COCAINE.

The author thought this drug of special value in the treatment of melancholia and of hypochondriac insanity. It should be administered hypodermically, in about grain doses. Its beneficial action on the melancholia was often almost immediate. A cocaine habit, like the opium habit, was liable to be formed, and it would readily take the place of the opium habit. The antidote of the drug was morphine.

The following papers were read by title: "The Brain of a delusional Monomaniac, who killed several Persons," by C. K. Mills, M.D.; "A Case of Destructive Lesion of the Tegmentum, Optic Thalamus, etc.," by H. D. Schmidt, M.D. Fifty or more longitudinal and transverse sections of the brain done up in glycerin, by H. D. Schmidt, M.D., were presented.

The President appointed the following committee on electrical dosage: Dr. G. W. Jacoby, chairman, Dr. R. W. Amidon, and Dr. W. K. Birdsall.

The Society adjourned to meet at the call of the Council at about the same time next year.

## Recent Literature.

*Modern Therapeutics of the Diseases of Children, with Observations on the Hygiene of Infancy.* By JOSEPH F. EDWARDS, M.D., etc. etc. Philadelphia: D. G. Brinton, 115 South Seventh Street. 1885.

This book is interesting as a compilation of the remedies used by some three or four hundred physicians in different diseases. As to its practical utility, we must express our doubts of the possibility of gaining much aid in special cases from its pages. On looking over the list of physicians quoted we are immediately struck with the idea that they are taken somewhat at random, and that they do not always impress us with that feeling of reliance as to their soundness of judgment, which is so necessary where a simple statement is made that such a physician treats such a disease with a certain remedy.

Diseases in children change so from day to day and hour to hour that much greater detail than is possible in a volume of this size would be needed to guide the physician through a difficult case, and the simple cases, as we all know, take care of themselves if judiciously let alone.

# Medical and Surgical Journal.

THURSDAY, JULY 2, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

283 WASHINGTON STREET, BOSTON, MASS.

## THE RELATION OF BACTERIA TO THE HUMAN ORGANISM IN HEALTH AND IN DISEASE.

In a former article the subject of fermentation was briefly considered, and the modern view, in opposition to the more ancient view of Liebig, stated. It may now be regarded as a datum of science that the alcoholic, butyric, acetic, lactic, gallic, and other similar fermentations are each due to a definite microorganism, and that, despite the seeming instability of all organic substances, these do not ordinarily break up into lower compounds, except under the agency of just such genera of microphytes as we behold in a drop of any decomposing liquid.

There is a marked resemblance between fermentation and putrefaction in the profusion of living particles developed during these processes. One of the most interesting chapters in the recently published *Life of Louis Pasteur*<sup>1</sup> is devoted to the history of the researches by which he proved the dependency of even such simple transformations as that of alcohol and water into vinegar on the growth and development of a particular fungus. Moreover, countless experiments, of which the familiar instance of canned meats is a sufficient example, have proved that the same relation holds between putrefying substances and the microscopical organisms that are found in them; if you exclude these there is no putrefaction.

The question, what relation these microscopical beings sustain to the higher organisms in health, is more easily answered to-day than it was a few years ago. Our knowledge of the "infinitely little," their life history, their properties, their conditions of living, has wonderfully increased of late, though still very imperfect. Mycology is beset with difficulties which human genius and industry are but slowly surmounting. Whether the ordinary fungi that seem to us so harmless may, under certain circumstances, develop into the deadly micro-

organisms that devastate society (assuming the truth of the germ theory), we know not. Certain it is that many species seem to be inoffensive to everything which has life and vigor, while they feed on dead or decaying substances. Some of the moulds — *aspergillus glaucus*, *mucor macedo*, *penicillium glaucum*, etc. — are of this character. Cells and mycelium are almost the sole elements of these fungi, which are aerobic, that is, can only live in free air. Other fungi are innocuous to animal life while devouring the vegetal. It is known that the whole tribe of rusts and mildews do attack vigorous plants. The *botrytis infestans* causes the potato rust, and the *oidium vitis* is the pest of vine-growers. In fact, all vegetables have their parasites, and the same is true of all animals; the highest are a prey to the lowest where the conditions are favorable for the nutrition and development of the latter, a state of perfect health being in general unfavorable. In reality health may be regarded as the expression of the vital integrity of an organism whose anatomical elements are able successfully to resist the incursions of the lower life. In the individual as in the race, to the higher and more evolved victory is temporarily assured, though defeat in the end is certain.

The immunity which the more complex and highly evolved organism possesses against the harmful assaults of the living ferments is relative: (1) To the quantity of the assailants. It is evident that in the struggle for existence between the living cells of an organic aggregate and the septic or pernicious microbes, the latter will be much more easily overcome if few in numbers; while, like the strongest and best-disciplined army, the healthy anatomical cells may be outflanked and overcome by an ever-augmenting foe. In whatever way bacteria may be introduced into the economy, or *whatever the kind*, it is quite possible for the healthy organism to tolerate them with impunity, provided the quantity be inconsiderable. (2) To the mode of introduction. The fermentiferous, putrefactive, or morbi-genous bacteria may be inhaled or ingested by a healthy individual without the least harm accruing thereby to the functions of the economy, provided that the fluids and tissues be in a normal state, and there be no special receptivity. There are abundant facts to bear out this statement.

With regard to the introduction of bacteria into the alimentary canal it is certain that when the stomach is healthy the gastric juice is inimical and destructive to them all. Moulds and septic bacteria may be often eaten with impunity. The Kalnuck Tartars live on raw, putrid fish or flesh of carrion, and are said to be a healthy race. Now such putrid meat swarms with bacteria. Koch claims that in perfectly healthy individuals even the cholera microbe when swallowed in food or drink is destroyed in the stomach. Individual experience would certainly seem to countenance this statement. It is

<sup>1</sup> *Life of Louis Pasteur*. By his son-in-law. New York: D. Appleton & Co., 1885.

only when the powers of the stomach are enfeebled and there is deficiency of gastric juice that the "comma bacillus" is able to penetrate the intestines and accomplish its mischief. Decroix even declared that the meat of an animal killed while suffering from splenic fever was innocuous; and confirmed his opinion by eating it with impunity. (If, however, the meat were thoroughly cooked, the microbes would be destroyed, so that the experiment to be conclusive should have been made with raw meat or meat underdone.)

The injection under the skin or into the blood of bacteria, and especially of such as are of great known virulence, is much more dangerous; but even such inoculation has been practised with safety. The ordinary septic microbes when so introduced are prone to give rise to septicæmia, especially when injected in quantities sufficient to overcome the resistance of the animal cells; but instances are not few where their inoculation has caused but slight temporary disturbances or none at all.

The results of the injection of the morbigenous bacteria may equally be nil. Everything depends on the receptivity of the organism. Some persons have a natural or acquired immunity against certain malignant parasites, which, when introduced into the bodies of other individuals, speedily find there a congenial soil. Science is not yet in possession of any very satisfactory explanation of facts of this kind. Certain it is that receptivity is far from being constant, and that the solids and fluids of the economy of even the most susceptible are quite soon exhausted of some supposed mineral or organic ingredient on which the life of the microphyte depends. Hence the protective value of previous attacks and "preventive vaccinations."

"He that understands the nature of ferments and fermentations," says Robert Boyle, "shall probably be much better able than he that ignores them, to give a fair account of divers phenomena of certain diseases (as well fevers as others), which will perhaps never be understood without an insight into the doctrine of fermentations."

Although all general diseases are accompanied by qualitative alterations in the blood, there are certain diseases in which the blood-changes so markedly partake of the nature of decomposition that it is proper to speak of them as *fermentations*; the analogy between the circulating fluids in these diseases and liquids undergoing fermentative decomposition out of the body being most striking and complete. The term *zymotic* is an appropriate one, for the blood of victims of these maladies is invariably found to have undergone to a greater or less extent certain gross changes, such as corpuscular disintegration, decrease of fibrin, increase of carbonic acid, diminution of oxygen; in some malignant epidemics (as of diphtheria) it becomes tarry, non-congluable, and sticky, and speedily putrefies when

withdrawn from the body. There is another characteristic which assimilates the blood of a zymotic affection to a fermenting fluid, namely, the power which its virus possesses of multiplying itself *ad infinitum* in suitable media. Take, for instance, a drop of anthracoid blood and inoculate with it a healthy animal: you may communicate the disease to this animal, infect a whole flock, and spread the pestilence over an entire country. Or if a drop of this splenic-fever blood be sown in sterilized yeast-water and cultivated, and a drop of this culture-fluid be sown in another flask of yeast-water, and so on, you will obtain a product which in the fiftieth generation shall be just as virulent as the original anthracoid blood. This is precisely the case with fermentations taking place under the influence of the *torula cerevisia*, the *mycoderma aceti*, the *cibris lactis*, etc. "A little leaven leaveneth a whole lump." Is this power of unlimited self-propagation peculiar to living beings? Are there any chemical poisons not of an "animated," "figured" nature, but of a soluble kind, which are known thus to reproduce themselves? Here, unfortunately, we have to confess to a lacuna in our knowledge. Sir James Fayer supposes the poison of snakebites to be a soluble chemical ferment; this poison clearly reproduces itself in the system of the person bitten, if it be true that the blood of the victim be infecting, as Sir James Fayer asserts. The virus of rabies seems also capable of similar diffusion and reproduction. Pasteur still resolutely affirms the microbiotic nature of rabies, and there is equally good reason for holding to the same view regarding snake-venom, but on these obscure questions we wait for more light.

The analogy, however, does not stop here. The alcoholic, lactic, and other like fermentations are each due to a particular microphyte, and if the specific fevers are the expression of fermentative changes in the blood, they must each have a different causal microbe. This early prevision of scientific medicine, which has for the past twenty years been the guiding hypothesis of workers in pathogeny, is now finding justification and verification every day.

#### THE NEW YORK STATE BOARD OF HEALTH.

GOVERNOR HILL has, much to the regret of all, vetoed the item in the supply bill of \$45,000 for this State Board of Health. His action was based on the statement of the comptroller that there was no deficiency which this amount was designed to cover; but the appropriation was not for an actual deficiency but for a deficiency that would arise during the year if the Board continued its operations on the present scale. The regular annual appropriation of \$20,000 is barely sufficient for the recording of the vital statistics of the State and other routine expenses. The additional amount was required for

carrying on the work of the investigation and suppression of disease, as will be seen from the following extract from the annual report: "Urgent appeals are frequently received from local boards of health and citizens of various parts of the State for advice and assistance in questions of supreme moment to public health, requiring for their elucidation skilled sanitary inspection and often exact analytical examination. As far as the pecuniary resources of the State Board have permitted, prompt response has been made to such appeals, but as they increase in number, lack of means compels reluctant neglect of some of them. Furthermore, under the duties imposed upon the Board to make inquiries in respect to the causes of disease, and especially of epidemics, and to investigate the sources of mortality and the effects of localities, employments, and other conditions upon the public health, it is evident that a system of sanitary investigation was contemplated far beyond the present possibility of attainment, but absolutely needful to enable it to take cognizance of the interests of health and life among the people of the State. Toward the fulfilment of these, the most important duties of the Board, the sum of \$15,000 is asked, and even with this, in view of a threatened epidemic visitation, the demands upon the Board during the coming year will probably exceed its power of compliance."

The effect of the Governor's veto of the extra appropriation was quite promptly illustrated. The very day afterward the secretary of the Board, Dr. Carroll, received a dispatch from Dr. Nichols, health officer at Plattsburg, stating that a case of smallpox had appeared there, and asking for sufficient vaccine virus for five hundred persons. Dr. Carroll was obliged to reply that the State Board of Health had no means to procure the virus, though he asked the New York City Board to answer the appeal. There was urgent need, he said, of an inspector at Plattsburg to examine the passengers of every train arriving from Canada, where smallpox is now prevalent; but under the present circumstances it would be impossible to provide one.

The State Board of Health has appointed Dr. Englehardt official chemist and analyst of beers and distilled liquors, and has issued a circular to all brewers and distillers in the State, accompanied with a copy of the bill, stating that the Legislature recently passed an act imposing upon the Board the duty of making, at least annually, an examination of samples of all such beverages made or offered for sale in every brewery or distillery in the State.

#### MEDICAL NOTES.

The *Lancet*, while disclaiming any desire to deal in matters of general politics, hopes little for the interests of medical science from the change of administration in England. Looking back on the last five years, it says that it is only an act of justice to

record the fact that seldom, if ever, within an equal period has the medical profession received so many honors from the hands of a Prime Minister as Mr. Gladstone has distributed, and acknowledges that for this measure of favor medical men are directly indebted to the enlightened and generous appreciation of services and usefulness shown by the gifted statesman, who is now, it is to be feared, finally resigning the control of public affairs.

"If the Conservatives should hold office," says our contemporary, "we are bound to confess that — all party views and sympathies apart — it would be absurd to expect that medical men and their opinions will count for much. The healing art has little interest for the *aristocratic* party in politics. To be a 'doctor' is to be beneath regard, unworthy of honor; and to speak of the interests of health, except in a meaningless phrase, is to introduce a topic too vulgar for delicate ears. Medicine, whether as a science or as a profession, has little to hope from the party which never once in six years conferred an honor on any member of the medical body; and, though it talked much, did nothing — or, if possible, less than nothing — for the advancement of science and the encouragement of those whose lives are spent in a ceaseless struggle to reduce to practice the fruitless aphorism, *Sanitas sanitatum, omnia sanitas*."

— A wealthy Lothario, who was blessed with a beautiful wife, called on a physician of one of our summer watering-places, to consult him about a severe pain in his back.

"What have you done for it?"

"Applied a belladonna plaster," replied Cæsus.

"Well," said the doctor, "give up the belladonna and stick to the Donna Bella, and you will be cured."

— A discussion which has aroused considerable feeling of late in England has been in reference to the pauperization and consequent disfranchisement of men who accept the services of Poor Law medical officers. Much is to be (and has been) said on both sides. The extension of the household franchise has given the ballot to a large number of persons who are earning barely enough to keep soul and body together, and who, in case of sickness, must receive public relief or none at all. A short illness may then defeat the obvious intention of the parliamentary reformers in the case of numerous individuals. Moreover, a desire to preserve the elective franchise may deter sufferers from contagious diseases from reporting their condition. On the other hand, the overworked Poor Law medical men see a chance in the proposed disfranchisement to remedy an evil of great magnitude, namely, the application for public assistance of many of the wage-earning class who could afford, if so disposed, to pay for their medical aid. An act of Parliament is called for to define medical relief on a fair and equitable basis.

## Miscellany.

### A RATBITE OF THE PENIS.

DR. GEORGE H. FOX tells, in the *Journal of Cutaneous and Venereal Diseases*, of a case in which a gentleman engaged in mercantile business was bitten on the penis by a rat while occupying a primitive sort of a water-closet in the basement of his warehouse. On examining the patient shortly after the occurrence, the writer found on the left side of the sheath of the penis a loss of substance three-fourths of an inch in length, which had evidently been produced by incisor teeth or some sharp, cutting instrument. The wound, still bleeding, was cauterized with fused nitrate of silver, and the fears of the patient were gradually allayed. The wound healed quickly, leaving a superficial scar. In a note received a few weeks later, the patient remarked that, although a ratbite might not be dangerous, the inconvenience of its presence on such a portion of the body could not be overestimated.

There is a moral in this story. A week after the bite occurred the wound looked very much like an ordinary chaneroid. It is naively asked: "Now what would the reader say if a respectable married man were to come to him with an apparent chaneroid of the sheath of the penis and state that he had had no illicit intercourse, but had been bitten by a rat?"

A second lesson drawn is to the effect that the physician who disbelieves in the vicious nature of the water-closet in connection with venereal disease might, in an exceptional case, be unwarrantably incredulous.

We are moved to add still a third moral, to wit, that a suitably contrived trap is shown to be necessary in a water-closet to prevent these lower organisms from escaping from sewers and finding lodgment in the human body.

### AN ENORMOUS GALL-STONE.

At a recent meeting of the College of Physicians of Philadelphia, Dr. J. H. Musser presented for Dr. Livingstone, of Columbia, Pennsylvania, a stone which was removed at the autopsy of a female, aged sixty-six years, who died of colloid cancer of the omentum. The carcinoma was recognized during life, but the presence of the gall-stone was not suspected. In addition to the malignant disease of the omentum, secondary growths were seen in the bile-ducts. One nodule completely occluded the common duct. The gall-bladder was firmly contracted around the stone, and a small fistula at the fundus communicated with its cavity and that of the peritoneum. The stone weighs 391 grains (or 25.6 grms.), and is three and one-third inches (or 8.5 cm.) long. The largest circumference measures 7.9 cm. The small end measures 5 cm. in circumference; the large end, 7.1 cm.

It is elongated cylindrical in shape, tapered at each end. The end of the stone corresponding to the neck of the gall-bladder shows the greatest reduction in its circumference, as seen by the measurement, and

evidently extended into the cystic duct, as half an inch from the point it is slightly curved. In the middle of the stone an abrasion, so to speak (not due to handling), is seen, the size of a five-cent piece. It shows three or four laminae of the stone. Both ends of the stone are rough, the body quite smooth.

### INFLUENCE UPON OFFSPRING OF INTOXICATION AT THE TIME OF CONCEPTION.

In the *Journal de Médecine* (March, 1885), we notice an account of some observations by Dr. Leutz, of Tournai, on this subject. He speaks of the importance of distinguishing between a state of chronic alcoholism and accidental or temporary intoxication. Some authors, among them Demeaux, have maintained that intoxication of the parents at the time of conception was one of the chief causes of nervous affections among the newborn, and go even so far as to say that the intellect and the moral sense are also affected. Convulsions are very liable to carry off such children, or if they live, epilepsy, idiocy, or imbecility develops. If the children grow up they are stunted, dull, depraved.

Dr. Leutz does not agree with these views in their full extent. He has observed that among the working classes, owing to the custom at the marriage banquet, the husband is almost invariably more or less intoxicated on his wedding night, and that while in this condition the first child is begotten; whereas the other children are not conceived under similar circumstances. There is not, however, any observable difference between the physical or moral makeup of the firstborn and of the later children.

### CASES OF RAYNAUD'S DISEASE.

At a recent meeting of the Clinical Society of London (*Medical Times*, May 30, 1885), Dr. Colcott Fox exhibited two adults affected with this disorder, and read notes on the cases. A woman, aged forty-one, of extremely nervous temperament, dated the commencement of the disorder from ten years back, but though this was the period when her attention was attracted by her pain, it is probable that she suffered from slight attacks for some years previously. In the earlier stages all her fingers continually went "like white wax." This condition of recurrent local syncope gradually gave place to local asphyxia, and the feet became involved. The fingers gradually lapsed into a state of chronic asphyxia, which was intensified by frequent attacks of more severity, often leading to "blood-blisters and ulceration." The nutrition of the phalanges has suffered greatly, so that her hands are crippled, the fingers are fusiform in shape, livid, shiny, and withered, the nails variously distorted, and the end phalanges much atrophied and almost immovable. The nose and ears are affected to some extent on exposure. Cold and nerve shocks are ready exciting influences. The second case, that of a man, aged fifty-one, was of considerable interest from the fact that, like one of Raynaud's cases, he suffered from diabetes. His hands were not deformed, but he had suffered for several years from "dead fingers." He sought Dr. Fox's advice

for symmetrical gangrenous patches on the skin, which recurred, and later for an attack of asphyxia of one great toe and lower third of the inner side of the leg, and then it was found that he had been attacked in a similar manner, though more severely, in the other toe, and on another occasion blood-blisters had formed beneath the ends of his toes. Dr. Fox concluded his paper by giving a reference to some cases which have been recorded as scleroderma of the extremities. A woman with the latter disease was shown to illustrate the difference between it and Raynaud's symmetrical gangrene of the extremities.

In the discussion which ensued, Dr. Barlow reminded the Society of three cases which he had brought before it in a previous session. From subsequent observation of these cases he had been led to some conclusions with respect to treatment, and especially by means of the continuous current. In one case, that of a man aged forty-two, in whom repeated attacks of the disease had caused almost complete inability to walk, he had employed the continuous current with very satisfactory results, a gradual improvement in the circulation having taken place during the eight months during which the treatment was applied, and remaining permanent after its discontinuance. He had found that the most satisfactory method of using it had been by the application of both poles of the battery to the affected part and by painting the surface with one of them. In two other cases he had employed the constant current by means of baths during the attacks of extreme pain, and had succeeded in cutting short the seizure at once. He had used nitrite of amyl, on the strength of Raynaud's opinion that the disease was due to spasmodic contraction of vessels, and, although the general physiological effects had been produced, there had been no relief afforded. He should recommend the use of the constant current persevered with for several weeks, and followed by frequent shampooing. He believed that its action was simply that of a local stimulus.

#### PERIODICAL CHANGE OF COLOR OF THE HAIR.

This phenomenon, already the subject of editorial comment in this Journal, has again been observed, and a case is reported in the *Lancet*. A young girl, aged thirteen, of an idiotic type, was admitted into the asylum at Hamburg, April 1, 1880, and died there in 1882. At the age of three she began to be affected with spontaneous movements like St. Vitus's dance, chiefly confined to the head and upper limbs. Between five and six she had become a well-marked epileptic. At four she was able to run around a table; but her powers of progression steadily diminished and the lower limbs passed into a condition of chronic stiffness. When in the asylum she had fits about every eight to fourteen days; besides, she experienced alternations of agitation and calmness, each of about a week's duration. During agitation the turgescence and redness of the face were most pronounced, the pulse full, skin warm, and actively transpiring, at the same time the mental condition being one of extreme obsti-

nacy. It was often remarked that the hair underwent decided changes of color; sometimes it was blonde and at others red, whilst the depth of these colors also varied. The alterations in color occurred in the brief space of two or three days; the first appearance of change was observed at the free ends of the hairs; the same tint of hair persisted for seven or eight days. Each of these periods of change coincided with a phase of agitation or sedateness. During the excitement the hair always had a red color, whilst during the phases of stupidity the blonde tint prevailed. The case appeared to be one of genuine pathological change. The paler hairs differed from the darker ones only in the presence of more numerous air-spaces. The structure of brain and spinal cord was much altered.

### Correspondence.

#### REDUCTION OF CONGENITAL DISLOCATION OF THE HIP.

Boston, June 26, 1885.

Mr. Editor, — Allow me to call your attention to one point in the editorial on congenital dislocation of the hip in the issue of June 11th. I refer to the sentence in which you speak of the reduction of the dislocation, "which has remained reduced ever since." This remark may possibly lead to some misapprehension of the facts of the case. It may be inferred that after the reduction had once been effected the bones were retained in their place. In truth the heads of the femurs were reduced many times, or in other words they were placed in their normal position by manipulation and extension every day at my morning visit. The daily displacements continued through the month of January, 1883, and until "about the middle of February, when it was found that the tendency to slip upward was greatly diminished, and that days elapsed without this occurrence taking place." It was at the period here referred to that the process termed in my paper the stage of excavation was put in force. This state of things continued, the dislocations (for now that the sockets had partially formed the displacements were true dislocations) taking place less and less frequently until the twenty-eighth day of March, 1883, since which date the bones have remained in position. Very respectfully yours,

BUCKMASTER BROWN.

[Possibly the sentence in the editorial referred to by Dr. Brown may be calculated to mislead the reader, but such an interpretation as suggested in the above communication was not intended. — Ed.]

#### IMPRISONMENT OF MEMBERS OF THE MASSACHUSETTS MEDICAL SOCIETY.

Nahant, June 28, 1885.

Mr. Editor, — Being the member of the Committee of Arrangements for the late meeting of the Massachusetts Medical Society who is responsible for the "imprisonment of members of the Society," kindly allow me to grant the information asked for, with it seems to me rather scant courtesy, by your correspondent of last week.

It is the long-established custom for the Fellows of the Society to walk in procession, in order of their seniority, from the hall where the annual meeting is held to the dining-hall. For the last two years, since the Society has met in the Institute of Technology, gentlemen coming after twelve o'clock in large numbers have crowded together in the lower hall, making it difficult to keep the procession in its proper order, on

account of the obstruction to its passage, and on account also of many Fellows joining the procession at a point far ahead of that to which their membership in the Society entitles them. It was for this reason simply that, at a few minutes before one o'clock, gentlemen were asked to leave the hall clear for the procession by retiring to the rear of the rope. The two large rooms used by the Treasurer and for the exhibit were left open; and as soon as the procession was formed, Fellows were at liberty to join it in their proper place. It hardly seemed to me the hardship that your correspondent considers it, and if he will remember that a committee is bound to consider the convenience of the majority, I think his opinion as to the magnitude of the affront may be modified.

The members of the Committee of Arrangements give very considerable time to making such arrangements as seem in their judgment wisest. The position is not one of great honor, and is certainly one of no

emoluments. As I am personally responsible for the particular arrangement your correspondent complains of, let me state that any "affront to the Fellows of the Society" was certainly unpremeditated; and the action was taken simply for the purpose of preserving the order of the procession, which it is impossible otherwise properly to maintain.

Please allow me also to correct certain errors in my communication of last week. The paragraph: "We are obliged to give a guarantee for a number of plates, not less than fifty in number, of those who are to be fed," should read: "We are obliged to give a guarantee for a number of plates not less than fifty in number than those who are to be fed." Secondly, I was not the chairman of the Committee of Arrangements, who is the Anniversary Chairman, and did not sign myself as such, but as

H. C. HAVEN,

Member of Committee of Arrangements.

#### REPORTED MORTALITY FOR THE WEEK ENDING JUNE 20, 1885.

Deaths reported 2,584: under five years of age 1,121; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 567, consumption 305, lung diseases 226, diarrheal diseases 250, diphtheria and croup 102, scarlet fever 59, measles 45, typhoid fever 31, malarial fevers 29, cerebro-spinal meningitis 17, whooping-cough 15, erysipelas 15, puerperal fever three, From measles, New York 20, Brooklyn nine, Philadelphia five, Chicago, New Orleans, and District of Columbia two each, Boston, New Haven, Lowell, Cambridge, and Lawrence one each. From typhoid fever, Philadelphia and Chicago eight each, Brooklyn and Boston three each, New York and Charleston two each, Baltimore, New Orleans, Providence, Lowell, and Lawrence one each. From malarial fevers, New York 11, Brooklyn five, Baltimore

four, Boston and New Orleans three each, Philadelphia, District of Columbia, Charleston, and Lowell one each. From cerebro-spinal meningitis, Chicago five, New York three, Worcester two, Boston, Baltimore, New Orleans, District of Columbia, Lowell, Cambridge, and Newton one each. From whooping-cough, New York and Brooklyn four each, Philadelphia and New Orleans two each, Chicago, Boston, and Fall River one each.

Cases reported in Boston: measles 11, scarlet fever 27, diphtheria 20, and typhoid fever seven.

In 11 cities and towns of Massachusetts, with an estimated population of 1,335,000 (estimated population of the State 1,355,000), the total death-rate for the week was 00.00, against 00.00 and 15.43 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending June 6th the death-rate was 20.5. Deaths reported 3,497; infants under one year of age 825; acute diseases of the respiratory organs (London) 290, measles 224, whooping-cough 130, scarlet fever 31, diarrheal diseases 32, fever 44, diphtheria 23, smallpox (London 34, Manchester 20, Hull one) 37. The death-rates ranged from 16.0 in Brighton to 35.6 in Manchester; Birmingham 23.3; Bradford 19.7; Hull 17.6; Leeds 19.4; Leicester 16.5; Liverpool 21.0; London 19.4; Manchester 33.6; Nottingham 23.4; Sheffield 24.6. In Edinburgh 20.6; Glasgow 25.2; Dublin 23.1.

For the week ending June 6th in the Swiss towns there were 30 deaths from consumption, lung diseases 29, diarrheal diseases 11, smallpox, diphtheria and croup each four, erysipelas and purpural fever three each, measles, whooping-cough, and typhoid fever each one. The death-rates were: at Geneva 10.1; Zurich 13.6; Basle 18.9; Berne 24.0.

CLINICAL NOTES ON OSTEOTOMY, WITH REPORT OF CASES.<sup>1</sup>

BY N. P. DANDRIDGE, M.D., OF CINCINNATI, OHIO.

OSTEOTOMY as now performed is an operation of recent growth, and it is only within the last few years that it has been very generally adopted. Practised as it is for the correction of deformities which, while they impair the usefulness of a limb, and more or less completely disable the individual affected, are in themselves rarely if ever the source of danger to life, the results of the operation and the dangers which attend it should be most carefully considered. We are already in possession of many accumulated facts bearing on these points, and extensive series of cases have been published by various operators with the object of showing the safety of the procedure and the eminently satisfactory results which have been obtained, extreme deformities being corrected and the disabilities depending upon them entirely removed.

Reeves, in his book on "Practical Orthopedics," gives a table of 493 osteotomies, and in commenting on it says: "I must mention that there have been no deaths, no joint suppuration, nor ankylosis. All the cases have made good recoveries with good position and motion. In many instances an addition of one, two, or more inches was added, either on one side or both, as circumstances dictated. . . . and when I add that suppuration only occurred in six cases, and that in four of them the traumatic form of measles or scarlatina supervened, I need say no more to prove the perfect safety of the operation in experienced hands."

Willett, in the last volume of St. Bartholomew's Hospital Reports, publishes "The results in a hundred cases of osteotomy," with only one death, one case marked "not improved," and two, "relapsed."

Poor, in his excellent work on "Osteotomy and Osteoclasis," gives his results in seventy-four linear and seventeen cuneiform osteotomies: "All the patients on whom these operations were performed recovered with the deformity corrected, except two cases of *genu valgum*, on which a Reeves's operation was done and in which the condyle could not be detached on account of the relaxed condition of the external lateral ligaments."

Of the seventy-four linear osteotomies there were eight cases in which more or less suppuration occurred, and the same condition followed in seven of the seventeen cuneiform osteotomies. Of the general results which have been obtained, he states that in 1,510 osteotomies performed for "the correction of deformities at the hip-joint, for *genu valgum* and tibial curvature," 1,118 were linear osteotomies, with 15 deaths, 22 cases of suppuration, and 17 cases of necrosis, a mortality of one per cent. (and not, as he states it, 10 per cent.); and 62 were cuneiform osteotomies, with 17 cases of suppuration and five deaths, a mortality of about 8 per cent. The combined mortality is 32, or a trifle more than two per cent. The above citations are quite suffi-

cient to show that the operation, in the hands of experienced men, has given most satisfactory results in relieving many hitherto irremediable deformities, and that the accidents which have followed are very few in number and the mortality slight.

Admitting, as I do, these facts most fully, the perusal of such long lists of successful cases must, I feel, give rise to a false sense of security in the performance of osteotomy which will surely lead to unfortunate results in the hands of those who have less experience, and the history of the following cases is given for the purpose not only of illustrating the advantage of the procedure, but of presenting at the same time the dangers which are run and of emphasizing especially the necessity for minute attention to detail in operating, by which alone these can be avoided.

Osteotomy is divided by Poor into linear and cuneiform. The former is a simple section made either with a chisel (osteotome) or saw, while the latter removes a wedge-shaped piece of bone. Cuneiform osteotomy undoubtedly possesses advantages in certain cases, but as my own experience is confined entirely to the former method, it is to this alone that my remarks will refer. My cases are given briefly in outline for the simple purpose of illustrating the treatment adopted, and without the intention of presenting any of the questions concerning the etiology of the affections described.

C. S., aged twenty-four; German; silver engraver by trade; presented himself at the Dispensary clinic of the Miami Medical College. His manner of walking was most ungainly and painful to see. The right femur was flexed at a right angle with the pelvis, with some adduction and was firmly ankylosed. By extreme curvature of the lumbar spine and throwing the body forward he was able to bring the toes of his foot strongly extended to the ground, and was then able to hobble about. When lying on his back on a table the spines of the lumbar vertebrae could only be made to touch its surface by bringing the thigh to a right angle with the body. There was absolutely no motion at the hip-joint, and the head of the femur, or rather what was left of it, for head and neck seemed to have disappeared, was dislocated upon the dorsum of the ilium. The circumference of the two legs was about the same, but the right thigh was considerably smaller than the left. He was induced to go to the Cincinnati Hospital, for the purpose of an operation to relieve his deformity. He entered the hospital April 1st, and gave the following history: At the age of two years he fell downstairs, and as a result of this accident was confined to bed for a long time with some trouble about his hip, for which he wore some kind of mechanical appliance. After leaving his bed he first went about on crutches, and used them until the age of seven, when he dispensed with them, and has since been able to go about in the manner above described. On the outer aspect of the thigh there is an old cicatrix which probably resulted from an abscess, though he cannot give any account of it. From this history it is probable that the deformity was due to an old disease of the hip-joint, which had resulted in destruction of the head and neck of the femur, with dislocation and subsequent complete bony ankylosis. No fresh trouble has

<sup>1</sup> Read before the Ohio State Medical Society.

been lighted up since childhood. The drawings, for which I am indebted to Mr. Holmes, one of the *internes* of the Cincinnati Hospital, give a very correct idea of the man's condition, and the improvement which followed the operation. April 7th the

femur was divided below the trochanters, the leg brought down parallel with the left, and a plaster bandage applied from the toes and carried up around the body so as to fix firmly the seat of fracture. The operation was performed by making an incision parallel to the long axis of the femur just large enough to admit the osteotome, which was then turned, and the transverse section of the bone made. The bone was very hard, and before it was cut through the instrument broke, leaving a piece wedged fast in the femur. To remove this the incision in the soft parts was enlarged and the broken portion chiseled out. The section was then continued, and when nearly through the bone was broken, by the exercise of some force. As the limb was brought down to the table it was found that a sharp edge of bone attached to the upper fragment projected just beneath the skin in very uncomfortable proximity to the femoral vessels.

To avoid perforation of the skin, which seemed inevitable, an incision was made over the most prominent part, and about an inch of the projecting bone cut off, and the wound at once closed with catgut. The original wound was partly closed, a drainage-tube being left in place, and both were then covered with cotton soaked in a bichloride solution. The plaster was so applied that the site of the first incision was left exposed, and for some hours there was a considerable discharge of bloody serum. The temperature only once reached 100.1°, and the pain complained of was never great. On May 9th the dressing was removed, both wounds were completely healed, and the union of the bone seemed firm, but as some pain was felt in both hip and knee

a fresh plaster dressing was applied again, and allowed to remain until the 19th. The boy is now able to move about on crutches, but as yet cannot bear his weight on the straightened limb, which is only an inch and a half shorter than the left.

In this case two mishaps occurred at the time of the operation, neither of which gave rise to any further trouble. The osteotome broke and the piece firmly wedged in the femur and broken off even with its surface had to be removed by enlarging the wound in the soft parts and cutting out a section of bone. This latter, however, was quite superficial, so the operation did not lose its character of a linear osteotomy. There was, however, more serious disturbance than would otherwise have been necessary. Willett speaks of this accident as frequently occurring, and says that the fragments of steel left in the bone give rise to no sort of trouble. The second mishap, the oblique fracture of the bone, leaving a sharp, projecting edge which threatened to perforate the skin, suggests the possibility of a like accident resulting in laceration of the femoral vessels as the limb is being straightened, especially in a case where there is great adduction present. The treatment adopted is, I think, the right one, namely, to cut down at once and remove the projecting edge. In a similar case which happened to Willett this was not done, and some months afterward there was considerable pain over the prominence left.

A further cause of trouble might arise from pressure on the femoral vein, and although no such case has been reported, the possibility of its occurrence must, I think, be admitted, and suggest the propriety of making the section as high up as possible, to thus diminish this danger by diminishing the resulting prominence of the lower end of the upper portion of bone.

I have had occasion in another case to make a section of the femur below the trochanters, in a girl aged thirteen, who, while bedridden from a necrosis of the left tibia, suffered a spontaneous dorsal dislocation of the right femur. The thigh was flexed at a right angle and was strongly adducted. Extreme lateral curvature had followed, and as the left knee was flexed at a right angle she lay in bed in a most distorted and pitiable condition, emaciated to the last degree from pain and from the constant discharge from the necrosed bone.

The femur was first straightened by section below the trochanters. This was found necessary, as section of the adductor tendons failed and manipulation for reduction of the dislocation was found entirely unavailing. The tibia was then at once operated on, and the necrosed bone removed, but as the disease extended so near the knee-joint and the shell of bone left was so slight, no attempt to straighten the limb was made for fear of fracture. Remarkable improvement in the general condition at once ensued, the femur quickly and firmly united, and after union there was limited motion at the position in which the head of the bone was lodged. At the end of eight months the child was well enough to travel to New York; at this time, however, repairs had not advanced sufficiently to enable her to stand on it, so the final result was not seen. I venture to predict from the result in this case that in

old cases of dislocation of the femur, where the malposition renders the limb useless and where reduction is found impossible, that an osteotomy below the trochanter will offer a better chance for a useful leg than any of the operations which have been proposed, especially in the young, where you may expect a more or less complete joint will be formed for the head of the femur in its new position, and if good union is procured at the point of section a more serviceable limb will be obtained than is probable after an excision of the head.

Mr. Adams has recently reported a case of excision of the head of the femur in a boy aged eleven, who suffered from an unreduced dislocation on the dorsum which had occurred spontaneously during the course of an attack of fever. The result was very satisfactory. In my case the condition of the child was such that repairs would have been hardly possible after such an operation.

A number of different operations have been performed for the correction of deformity at the hip-joint. I need only mention section of the neck by means of a narrow saw and the same operation with the chisel by Golding Bird. The infra-trochanteric section of Gaut, in which the object is to cut the femur below the insertion of the psoas magnus, and the partial section and fracture suggested by Reeves below the trochanter major. Adams's operation is not applicable where the head and neck have disappeared as the result of disease, or where there is an exuberant deposit of new bone forming hard nodules or spiculae around the femoral neck, itself entire."

Poor has analyzed the results which have been obtained. Sixty-eight sections through the neck gave six deaths and six failures, and sixty-four linear osteotomies below the trochanters six deaths and four failures; while thirty-three cuneiform osteotomies at the same position were followed by five deaths and two failures. He remarks, however, that these results exaggerate the danger, as twelve out of the seventeen fatal cases occurred prior to 1877, when experience in the operation was quite limited. After the section the limb should be placed in a position of slight adduction if shortening is present, for the obliquity of the pelvis will afford some compensation by producing an apparent lengthening of the limb. The operation should not be performed until all inflammatory action is over, as in some cases a rekindling of the old trouble has led to a fatal result, and the possibility of this has been urged as an extra advantage for the line of section proposed by Gaut, as being further removed from the seat of disease.

The two following cases present examples of great deformity from bowleg occurring in two sisters, the trouble in both commencing after scarlet fever. The father and mother and six brothers and sisters are free from all deformity. These girls entered the hospital on the same day as the man whose history has just been given, and the oldest was operated on at the same date, and the youngest a week later.

E. W., age sixteen; American; well developed and muscular. Both legs markedly bowed; when standing erect the inner condyles are separated six inches. The legs are short in proportion to the thighs, and measure only twelve inches from the

sole of the foot to the lower edge of the patella. The deformity began at the age of seven, after an attack of scarlet fever. She has been subject to fits. There is, she says, no spasm, but that she faints and then lies perfectly quiet. These attacks must, I think, be hysterical, as she is morose and very sensitive about her condition. The deformity seems due entirely to curvature of the tibia. At the upper epiphysal line the curve is so abrupt that it is almost angular. In the lower third there is also a decided incurving of both legs. The deformity is greatest in the left leg, and this is most marked in the upper portion. The toes point somewhat inward when the feet are held apart in standing.

Linear osteotomy was performed on both legs April 7th. The point selected for the section was at the most prominent part of the upper curve, and on the right was three inches below the lower edge of the patella, and on the left two inches. In each leg the fibula was cut first. The bones were very hard. The legs were at once completely straightened and put up in plaster of Paris. The course of the case was uneventful, and practically without fever. The bandage was removed May 9th, and the wounds found healed. Side splints were applied for a few days, and the girl was allowed to get up on crutches. The knees are now separated one and five-eighths inches. This is due largely to the curvature in the lower third. The girl is now on crutches, has lost her moroseness, and is highly gratified at her improved condition and appearance.

The following case, sister of the one just reported, illustrates the possible disastrous consequences of the operation:—

E. W., age fifteen, presented exactly the counterpart of her sister's condition, except that the degree of deformity was less, the condyles being separated five inches, and she was more active and less awkward. The deformity began at five years of age, after scarlet fever, from which she was confined to bed for a long time. The operation was made April 14th, the left leg first attacked, and the fibula readily cut through. The section of the tibia was then commenced upon its anterior surface, about an inch below the tubercle, and after the bone had been partly cut through an attempt was made at fracture. This was unsuccessful, and the chisel was again resumed. Several times attempts were made to break the bone, as the section seemed far enough advanced to permit of fracture. The bone was very hard, and considerable force was required to drive the chisel. Suddenly free arterial hemorrhage occurred, and, as this continued, the external wound was enlarged, and search made for the bleeding vessel. The hemorrhage came from the outer side of the tibia, and was temporarily controlled by a sponge on a pair of forceps passed deeply into the wound, and further pressure made by a bandage around the limb. The section of the bones of the right leg was now made, and the limb readily straightened, and at once put up in plaster. The bleeding by this time had come through the bandage on the left leg. The bandage and sponge were therefore removed, and at once blood welled up freely. The wound was enlarged, and an extensive and deep dissection made in the muscles on the outer side of the tibia, but still the bleeding point could

not be found, blood all the time coming up from the bottom of the wound. After persevering search a pair of hæmostatic forceps was passed deeply by the side of the bone, and the tissues grasped at a point from which the most profuse bleeding came, and partly arrested it. The complete arrest was only effected after a second and third pair of forceps had been employed at points slightly separated. Further section of the bone was given up, and the wound dressed, with the forceps still in place, after having been thoroughly washed with a bichloride solution. It was hoped that the bone might be broken after some days, or, if that was not possible, the section could be resumed when the danger of hæmorrhage was over.

The child passed a restless night, more, however, from pain caused by the plaster bandage on the right; this was relieved by loosening it over the foot and ankle.

In the morning her temperature was 102°, and it was necessary to draw her urine. The fever increased, and the following day the dressing was removed from the wound in the left leg and some badly smelling pus escaped. The forceps were left in place until the 17th, and when removed slight bleeding occurred, and in the bite of one of them a mass of tissue resembling a short section of a vessel was found. There was now considerable suppuration. During the next few days some improvement occurred, and the patient took nourishment, which she had at first refused. On the 20th, some hæmorrhage came on, but was controlled by pressure. The alarming symptoms, however, increased in severity, the temperature reached 104°, and a pocket of pus, which had formed on the outer side of the leg, was opened under ether in order to secure free drainage. This, however, did not avail, and the septic symptoms continued, and she died April 23d, nine days after the operation. The autopsy was made by Dr. Eichberg. Some patches of bronchopneumonia were found. The right leg at the seat of fracture was free from inflammatory action. The left leg contained an incision four inches long, at the bottom of which was a pus cavity, large enough to hold a walnut filled with clotted blood. The tissues about were infiltrated with clotted blood and were broken down. Posteriorly extensive hæmorrhagic infiltration had occurred and some œdema.

The posterior tibial artery was found lying directly on the surface of the tibia, and was partly cut through. The vein was completely severed; this was probably due to the forceps, and the tissue spoken of above was a section of this vessel. The tibia itself was thickened transversely, which accounts for the manner in which it resisted the several attempts made to fracture it when the division had reached a point at which the bone of the opposite leg readily yielded. The hæmorrhage which occurred at the time of the operation was due to a wound in the posterior tibial artery made by the osteotome, which had passed entirely through the bone. The artery at the level of the section is normally separated from the tibia only by a thin layer of muscle, and in this case the extreme hardness of the bone made it impossible to judge where the vessel had cut its way completely through the bone. Poor mentions a case in which he cut the anterior

tibial artery, but gives no details showing how the hæmorrhage was controlled. I have not been able to find mention of the occurrence of the accident I have reported.

In this connection the directions given by Poor I regard as of great importance. "It is," he says, "best to begin to divide from the crest inward," and "care should be taken that the osteotome does not extend beyond the outer border of the crest, as the anterior tibial artery may be nearer to the bone than normal, and is liable to be divided. I had this accident happen in my first case. After the bone has been divided through two thirds of its thickness the section can be completed by fracture." By following this advice the osteotome will be constantly directed away from the vessels, and it will be well to try and avoid cutting through the outermost layer of bone and make the section more complete on the inner side. Great care should be exercised to avoid complete perforation of the posterior shell at any point, and for this object the chisel should be as thin as consistent with strength, for the more wedge-shaped the cutting-instrument is the greater will be the resistance, and the harder it will be to appreciate when the section is complete and the chisel edge has passed entirely through the bone.

Time prevents me from presenting the question of osteotomy in correcting the deformity due to knock-knee. I have had but a single case, the ultimate result of which was entirely satisfactory. In this case the elongated inner condyle was cut through by a saw, as proposed by Ogston. In another case recently operated on by Dr. Comer, section of the femur was made above the condyles. The child is now running about. Professional opinion seems to have settled upon this last operation as the one best suited to the majority of these cases, and it is the one I should myself prefer.

My purpose in presenting the histories just recited has been to bring the subject of osteotomy before the Society in the hope of eliciting a free expression of opinion on the many important and interesting questions connected with this subject, which time has prevented me from even attending to; and in conclusion I will only add that, while advocating most strongly the operation in appropriate cases, I deprecate emphatically the idea that it is entirely unattended with danger, and, on the contrary, would emphasize the fact that, without extreme care and the skill which experience alone gives, it is liable to be followed by most disastrous results. Not only does the section of bone demand the utmost care, but the whole operation should be so performed as to protect the patient from the danger of suppuration and septicaemia, if accidents such as I have recorded should supervene. I will venture to assert that there are few operations in surgery in which success depends so much upon personal experience as will be found to be the case in the procedure under discussion.

—The Massachusetts Board of Health, Lunacy, and Charity has issued a circular in regard to cholera for the guidance of local towns and of individuals in case of an invasion of this disease. They request that, in the event of any attack of cholera, the fact be reported to them without delay.

TEMPERATURE OF THE INSANE, ESPECIALLY IN ACUTE MANIA AND MELANCHOLIA.<sup>1</sup>

BY WALTER CHANNING, M.D.

## SUBACUTE MELANCHOLIA.

CASE III. Miss C., thirty-eight years old. No heredity. Second attack. For many years has been the subject of nervous prostration. Has always had severe headaches, at present of a neuralgic type. Has now hallucinations of hearing, with loss of memory and mental confusion. Is anæmic, reduced in flesh, and is generally in poor physical condition.

Immediately after admission this patient's temperature was 99.2°, pulse 90. For a few days the evening temperature was higher than the morning by half a degree. After this time the morning temperature was the higher and this continued with hardly an exception for twenty-one weeks. The average difference between morning and night has been about a degree. Pulse ranged from 80 to 90 in this case. After the first six weeks the hallucinations disappeared and the patient has since been suffering from headache and nervous prostration.

## ACUTE MELANCHOLIA.

CASE IV. Mrs. D., sixty-eight years of age. Four children. No heredity. Attack followed domestic affliction. Has various delusions in regard to her poverty and her own wickedness. Considerably excited on admission. In good physical condition. The temperature in this case began at 99.2°, pulse 118. For six weeks it ranged between 97.1° and 100°, touching either extreme only once, and maintaining a mean of about 98.3°. The pulse averaged 90. The difference between morning and night averaged about one degree. During the first three weeks the temperature was always higher at night than in the morning. Every day the variation was quite uniform. Moderate excitement continued during this time and increased, but the patient was able to get out of doors quite often, and though always distressed about her sins, could eat, sleep fairly well at night on a small amount of medicine, and read the daily paper.

On the twenty-fourth day a new set of delusions of a painful character developed themselves concerning her immediate surroundings. The excitement became intensified, and especially showed itself in her excited movements. The effect on the temperature was very marked, destroying its hitherto regular remissions and exacerbations, also the regular daily rise from morning to night. This type continued now only about three quarters of the time.

On the forty-fifth and forty-sixth days the excitement had further increased and the patient was rather noisy and violent. The temperature made a jump from 98° on the morning of the forty-fifth day to 102.3° on the evening of the forty-sixth. The pulse rose from 96 to 111. On the morning of the next day the temperature fell to 100°.

Both before and after these days the general excitement was considerable, but not particularly more on these days than several others, yet the temperature never again exceeded 100.3°, except on

the fifty-third day, when it reached 101.4°. After this time there was a decline to normal, with much less excitement, though painful delusions were still very numerous. After remaining at normal for two days there was again a rise to a mean of 99°. The increase after the thirty-seventh day was with one exception from morning to night.

The great irregularity of temperature and its considerable degree of elevation were undoubtedly directly due to the mental and motor excitement, though, as I have said, I noticed no marked change on the day of the greatest rise. The case seems to be one where the general character of the temperature is the peculiarity of the attack, rather than its occasional unusual elevation.

## ACUTE SUBACUTE MELANCHOLIA.

CASE V. Male; twenty-eight years. Terrible mental distress. Range from 99° to 99.2°. Pulse averaged 80. Temperature irregular in type.

## ACUTE SUBACUTE MELANCHOLIA.

CASE VI. Female; thirty-seven years of age; married; one child; tired of life and had tried to kill herself. Temperature taken in the axilla. Range from 96.1° to 99.2°. Always lower at night by one half of a degree to a degree.

## ACUTE MELANCHOLIA.

CASE VII. Female; thirty-seven years of age; single; delusions as to her wickedness. Range of temperature taken in the axilla from 96.3° to 98.3°. Lower at night by four fifths of a degree.

## ACUTE MELANCHOLIA.

CASE VIII. Female; thirty-nine; married. Has committed the unpardonable sin. Refuses food. Temperature taken in the axilla. Range from 95.2° to 98.4°. Temperature uniformly lower at night than in the morning.

These cases will serve fairly well as illustrative instances of the temperature in the forms of insanity under consideration.

From the observations I have been able to make in cases coming under my notice, I believe that the temperature in insanity, though not pathognomonic, is characterized by certain features in the different varieties of the disease, which are peculiar to those varieties. I believe, with Dr. S. D. W. Williams,<sup>2</sup> who had records of several hundred cases of insanity, that there is no defined cycle of temperature in any of the forms of insanity, acute or chronic; but I can hardly go as far as he does when he says:

"In reviewing my labors with the thermometer in insanity, I cannot but own that its utility as an aid in mental disease is nil, whether as to diagnosis or treatment." He then adds: "But as an aid to diagnosis in other diseases complicated with insanity, its utility is very great."

I have already intimated that I have found the thermometer of utility in treating cases. I have been aided, especially in cases of high temperature where touch was entirely inadequate, to determine the rise by two or three degrees. In my opinion baths and wet packs are used too rarely in this country in treating acute cases of insanity. In such

<sup>1</sup> Concluded from p. 1.<sup>2</sup> London Medical Times and Gazette.

cases the thermometer is the safest guide when and how long to employ them.

In ascertaining complications, the thermometer will be of greater service if we use it systematically from the admission of a patient, rather than if we resort to it after other symptoms suggest their presence. In this way we can forestall the other symptoms to a certain degree, and earlier make a diagnosis.

As to the character of the temperature in the forms of insanity under consideration, the following conclusions may be drawn:—

In acute mania there is usually elevation of temperature to an uncertain degree. It is of the direct type: that is, higher at night than in the morning, as a rule. There may be striking exceptions. The maximum point is reached early in the disease. The mobility of the temperature is considerable, especially in severe cases: from one to five degrees. These marked fluctuations taking place at one to two degrees above normal, with great irregularity, and an occasional exacerbation to four and five degrees above normal, are to some extent characteristic.

The occasional exacerbations indicate increased intensity of symptoms probably, especially those of a motor character. In favorable cases, considerable remissions shortly follow.

In this form of disease the periods of Wunderlich can often be followed out with some accuracy.

Probably in many cases the thermometer gives reliable data for prognosis looked at from Wunderlich's standpoint.

Clouston<sup>3</sup> regards the temperature of acute mania as coming third, in height phthisical mania and general paralysis preceding it.

#### MELANCHOLIA. — ACUTE AND CHRONIC.

The characteristic of this form of insanity is the inverse type of temperature. I have found this to be the case pretty uniformly in the patients coming under my observation both when the temperature was taken in the axilla and mouth. The only exception I have found was in Case IV., where the excitement was intense, and where perhaps a more proper name for the attack would have been *acute mania*, with delusions of a depressed character or the *lypenmania* of Esquirol.

Writers differ very much as to the temperature in melancholia. Williams<sup>1</sup> says there is a very decided diminution in temperature, especially in melancholia attonita. "For days and days," he says, "you cannot register more than ninety-four or ninety-five degrees. Sometimes a very sudden fall is followed by excitement." I have never happened to observe this.

Clouston<sup>2</sup> says that the evening temperature of every form of disease is higher than in health, which has not been the case in my experience. He also says that the great characteristic of all forms of insanity is that the difference between the morning and evening temperatures is less than in health, owing to the rise of the evening temperature, and not the lowering of that of the morning.

Tamboni<sup>4</sup> has only found the *direct* type of tem-

perature in his 4,000 observations, though he alludes to the *inverse type* being spoken of by others. Buckhardt, he says, has found a low temperature principally in *lypenmania*, and Bechterew in *idiocy* and *dementia*. The mean temperature found by him in the insane is higher than that of any other writer, he says, which he ascribes to having taken all his temperature himself.

"If we except the increase of temperatures in paralysis and in the acme period in acute mania," he says, "which can be explained by irritation of the so-called cortical thermic centres, there is a lowering of temperature in insane people, which may be called *hypo-thermia*, either relative or absolute."

The low temperature at night is probably explained at least in part by the asthenic character of melancholia. Wunderlich<sup>5</sup> speaks of the "descending type" of temperature, in which the thermometer remains below the normal. This form is seen in inanition, marasmus, extreme anæmia, etc. Macdonald<sup>6</sup> found the temperature lower at night, in cases of general paralysis of the asthenic type.

Though the general temperature of melancholia is lower than of other forms of insanity, it may sometimes not fall below normal, except very rarely, during the whole attack. In most cases, however, the range would be from 96 to 99 degrees, sometimes much lower.

The pulse varies in both these forms of insanity, often very indirectly following the temperature. Sometimes it will show but a slight gain, with a considerable elevation of temperature. Other times, again, with a diminution of temperature. Again, it may show no change with a decided rise of temperature. The conclusion of Clouston<sup>3</sup> seems to accurately cover the ground as to the pulse. He says: "The average frequency of the pulse in the various forms of insanity, corresponds with the mean temperature, but the rise in the evening temperature has no corresponding rise in the evening pulse."

#### REPORT ON HISTOLOGY AND EMBRYOLOGY.

BY CHARLES SEBOWICK MINOT.

As this report is the first on the progress of these sciences to appear in this journal, it is appropriate to review the change of tendencies which has occurred during the past few years and so completely revolutionized the domain of morphology that it no longer appears at first sight like the same field of science. In fact, a generation ago the investigations were chiefly occupied with the problems of gross anatomy, and modern histology was in its early development, while microscopic anatomy has recently become the leading department. The perfecting of old methods and the introduction of many new and better ones, in connection with the applications of the microscope to the study of anatomy, enable us to undertake numerous and important researches which have hitherto been impossible. The improvements in two directions are especially important:

<sup>5</sup> Observations on the Temperature of the Insane.

<sup>6</sup> Observation on the Temperature of the Insane.  
Op. cit.

(1) in methods of staining; (2) methods of making series of sections. We have at our command at present the means of dividing any organic structure of moderate dimensions into a complete series of very thin and well-colored sections. These sections can be made with such regularity that they will practically all be of uniform thickness, and hence can be used for the purpose of a perfectly exact geometrical reconstruction of the original. By such means the anatomy of organs, such as the brain, the kidney, etc., can be studied with a thoroughness and precision impossible to attain by mere dissection. We have, then, a new field open to research—the field of microscopic anatomy, which is quite distinct from histology proper. The new possibilities are especially valuable to the embryologist, for embryos are too small to be sufficiently examined by dissection, while their size and consistency preëminently fit them for section cutting, and by serial sections we can examine both the anatomy and histology of every part, which was previously impracticable.

What can be done for the time being is being done; that is, the most important current work is based upon serial sections and the new staining-methods. Let us glance for a moment at these new aids. The foremost place, as an addition to the resources of the microscopist, unquestionably belongs to celloidin, as an imbedding material, because it requires no use of heat, allows unlimited staining of the sections, and permits our making sections of loose parts, which the celloidin in the section will keep in their exact relative positions, and further permits making thin sections of large area. Paraffin, which has hitherto been the principal imbedding substance, requires the use of heat, and is not suited for any but small objects. The use of celloidin was first suggested by Duvul; but its introduction and the development of its technique are due to Schiefferdecker. The second place in importance must be assigned to the new hæmatoxyline stains, based upon a combination of various salts with the dye, and subsequent washing of the tissue with ferricyanide of potassium. These methods were discovered and introduced by Weigert; and, although their application has been much simplified, we should not fail to recognize their immense value and our indebtedness to Weigert. The best results are obtained, according to my own experience, by soaking the sections for five or ten minutes in a nearly concentrated solution of acetate of copper, when the sections are washed quickly in distilled water and then placed for the same time in hæmatoxyline (one per cent. in ten per cent. alcohol), and finally washed out in Weigert's iron solution. The whole process is rapid and achieves a differential coloration unequalled by any other reagent.

Numerous other scarce less important improvements of technique have been made. Some idea of their number and variety may be derived from an examination of Fol's new and invaluable *Lehrbuch der vergleichenden mikroskopischen Anatomie* (Leipzig, 8vo., Engelmann, 1881-86), the first part of which, comprising over two hundred pages, is devoted to technique. This work is one of remarkable merit. It is an exhaustive compilation, made with judicious criticism, and written with admirable

clearness and precision. Defects of course it has, but they appear to be neither numerous nor, so far as observed, important. They are certainly not sufficient to lessen the cordiality of our commendation.

We proceed to consider briefly a few special discoveries:—

#### DEVELOPMENT OF THE UTERUS AND VAGINA.

As is well known, by the end of the second month the Müllerian, or female, ducts of the fœtus approach at their lower ends the Wolffian, or male, ducts and pass down to the urogenital sinus, which is represented in the adult female by the vestibulum. The four canals, together with the connective (mesodermic) tissue by which they are surrounded, make what is known as the *genital cord*, the upper limit of which is just below the insertion of the round ligament. In man the genital cord is the commencement of both the uterus and vagina; within the cord the two Müllerian ducts unite in the median line, forming a single canal; the upper portion of this canal becomes dilated into the uterine cavity, the lower portion develops into the vagina; the mesodermic tissue of the cord is converted into the muscular and connective tissue layers of the adult passages; the Wolffian ducts atrophy, they usually disappearing completely, though sometimes persisting as rudiments of greater or less extent, and are then known as Gärtner's ducts, and lie imbedded in the walls of the uterus and vagina.

The conversion of the genital cord into the uterus and vagina has been thoroughly investigated for the first time by Tonneux et Legay.<sup>1</sup> Their results are as follows:—

The fusion of Müller's ducts commences at the lower end of the middle third of the genital cord, and thence progresses most rapidly upward and more slowly downward. The lower ends fuse last; sometimes they do not fuse at all, thus producing the biperforate hymen, one of the numerous malformations which are explicable as arrests of development. The inferior extremities of the Wolffian ducts unite with the fused Müllerian canals, and thus participate to a small extent in the formation of the vagina. The utero-vaginal canal elongates steadily and expands transversely, especially in the vaginal portion; at the end of three months it measures 5 mm.; three and one-half months, 10 mm.; four and one-half months, 20 mm.; eight months, 30 mm. By the beginning of the fourth month the histological differences in the epithelium are evident; the vaginal half of the tube is lined by a stratified pavement epithelium, passing over gradually into the cylindrical epithelium of the uterine half; but during the eighth month the passage becomes quite abrupt, as in the adult. During the fourth month the vagina becomes flattened so that the dorsal and ventral surfaces are brought into contact, and, curiously the epithelium grows together, completely obliterating the lumen of the vagina; this lamina of epithelium makes a cup-shaped expansion at its upper end, this cup embraces the lower end of the uterus, and thus the projection of the cervix into the vagina is developed, for when the solid epithelium

<sup>1</sup> Tonneux et Legay, *Mémoire sur le développement de l'utérus et du vagin en l'enfance principalement chez le fœtus humain*. *Bulletin du Journal de l'Anal.*, 1889, 230-286, Pl. XX. XXX

of the vagina is finally cleft again (fifth month), the fissure extends through the epithelium, forming the cup. The folds of the uterus known as the arborescences, make their first appearance early in the fourth month, and are asymmetrical in such a manner that the cavity of the uterus, as seen in transverse section, is S shaped. Near the end of fetal life the epithelium of the cervix gradually acquires a mucous differentiation, and thus is secreted the plug of mucus found in the os uteri at birth. Glands appear in the cervix but not in the body of the uterus. The differentiation of the muscularis and mucosa commences with the sixth month.

Cadiat<sup>2</sup> has also published an article on the uterus, but it contains little of value. It may be noted, however, that he asserts that the glands of the body of the uterus are developed early in fetal life. I believe this opinion to be erroneous.

From a morphological standpoint the development of the human uterus is of very great interest. The first stage, the two Müllerian ducts nowhere fused, is the permanent condition in the lowest mammals (monotremes). The fused ducts, before their differentiation into vagina and uterus, represent the second stage, and is an advance above the conditions found in the monotremes and marsupials, but represents the lowest phase in the placental mammals. Here a devariation takes place; on the one side of the series the genital cord produces the uterus (primates and man), which is therefore single and median; on the other, the Müllerian ducts outside (above) the cord becomes the uterus. Therefore the uterus of most mammals of the placental division is not strictly homologous with that of man and his allies. The human uterus must, therefore, be considered as derived directly from a type quite low down in the mammalian series. We thus have another item of evidence tending to show that the line of evolution, which culminates in man, diverged quite early from the lines of the other mammalia. The conclusion is borne out by the evidence afforded by paleontology.

#### MORPHOLOGY OF THE HEAD.

For a long time an erroneous theory of the composition of the head was taught. According to this theory the head was supposed to be composed of vertebral segments, still recognizable in the bones of the skull. Three segments were generally accepted, the bodies of the corresponding vertebrae being the basi-occipital, basi-sphenoid, and pre-sphenoid bones. Some writers even assumed other similar vertebrae (one, two, or three) in front of these. It is now certain that the number of segments is very much greater; this discovery is due first and foremost to the investigations of Gegenbaur on the visceral skeleton of selachians. No satisfactory evidence has yet been found to show that the portion of the head in front of the pituitary body is segmented, but all of the head behind it is certainly made up of segments so completely fused as to be recognizable only in the embryo. It seems probable that during the evolution of vertebrates segments have been taken up from what was originally the cervical region and added to the hind end of the

head; the brain and skull have thus grown at the expense of the neck.

The number of segments was first determined by ascertaining the number of cranial nerves having a segmental character. The foundations of these determinations were laid by Gegenbaur. The elucidation of the homologies in the higher vertebrates is mainly due to A. Milnes Marshall. The results obtained by these and other authors will be found in the anatomical textbooks. One of the nerves thus given the value of a segmental nerve is the hypoglossus. August Frioriep,<sup>3</sup> however, has shown in three memoirs, remarkable for their ability, that the hypoglossus of mammals, at least, is a compound nerve made up by the fusion of three spinal nerves, and that the relations of other nerves in the head is different from what has been hitherto assumed.

In his first investigation Frioriep found evidences of three distinct protovertebrae, in ruminant embryos, in front of the first spinal or cervical nerve, and behind the vagus. (It should be remembered that *protovertebrae* have nothing to do with vertebrae, but are merely the primitive *muscular segments*.) In front of each of the three protovertebrae is a distinct set of anterior nerve roots, which all unite into a single trunk—the hypoglossus. Over the posterior of this set of roots is a dorsal ganglion, which also unites with the same nerve, and resembles the spinal ganglia in position and shape, although smaller in size. The hypoglossus must therefore be interpreted as the product of the fusion of three spinal nerves. As is well known, it makes its exit through the occipital bone, which, in its turn, must be regarded as the product of the fusion of several vertebrae. This again forces us to the conclusion that the skull is not identically composed in all vertebrates, but that in the mammals portions of the primitive cervical region have been added to the head. In mammals, then, the head is made up of at least three regions: (1) the pre-pituitary (or trabecular) region, bearing the nose and eye and corresponding to the upper face; (2) the pseudo-vertebral region, which gives off the nerves, namely, trigeminal, facial, glossopharyngeal, and vagus, supplying the visceral arches or pharyngeal (branchial) clefts; the vagus is now known to be a compound nerve; (3) the vertebral region, that of the posterior part of the occipital bone, and of the hypoglossal nerve. The ganglion of the hypoglossus is not permanent. It is always smaller than the spinal ganglia, but for a while it enlarges with the growth of the embryo, then remains stationary, and finally atrophies.

In his second paper Frioriep continues his researches on the morphology of the head by studying the origin and metamorphoses of the anterior vertebrae in the embryo chick. The first part of the essay gives the actual observations made, thus recording the raw material of the investigation; the second part (p. 215) presents the connected history deduced from those observations. In his first paper the author committed the error, surprising on the part of one so careful and skilful, of connecting the protovertebrae (that is, primitive muscle plates)

directly with the formation of the vertebrae. He now has made the necessary correction, and has adopted the designation "*primitive Wirbelbogen*" for the first *anlagen* of the vertebrae. The *Wirbelbogen* arise independently of the *protovertebrae* and before the bodies of the vertebrae, as two lateral masses inclined outward and tailward, so that they in part overlie the pair of muscle plates (*protovertebrae*) next behind the vertebra to which they belong. The lateral masses become united by a band of tissue extending across below the chorda. The change of the completed *bogen* into cartilage goes on during the fifth day of incubation. Toward the end of the same day the body of the vertebra appears behind the *bogen* and below the chorda as an accumulation of chondrogenic tissue; this continues to grow until the chorda is enveloped and a union established at the cephalic end of the vertebral body with the *bogen*, the hypochordal band between the *bogen* having first disappeared. These processes are completed by the eighth day, during which the neural transverse and articular processes grow out. Two points are especially important: (1) the double origin of each vertebra—the phylogenetic significance of this fact still remains to be elucidated; (2) the vertebrae do not arise out of a continuous mass enveloping the chorda, as maintained by Gegenbaur; on the contrary, the definite vertebralization is marked from the first.

The first two cervical vertebrae are tardy in their development, the first more than the second, but like the rest they have a double origin, but their ultimate development is unlike that of the other vertebrae. The *bogen*, with their hypochordal band of the first vertebra, grow up into the atlas, but the corresponding body *anlage* unites with the second vertebra and so forms the epistropheus. What is here called the "*bogen*" answers, as is evident, to only a part of the body of the ossified vertebra.

In the occipital region four vertebral *anlagen* can be recognized, with a muscle plate (*protovertebra*) in front of each, and a fifth plate behind the fourth, between it and the atlas. From in back forward the distinctness of these structures and their size diminishes. The third and fourth plates have each a nerve, the fifth (post-occipital) is supplied by the first cervical. These three nerves, and the second cervical also, have only ventral (motor) roots, and have lost their posterior roots and ganglia; this peculiarity of the cervical nerves appears to have been hitherto overlooked. The occipital vertebrae never attain complete separation, but fuse while still connective tissue, making the occipital *anlage*, which develops further in the known manner. Frioriep thus demonstrates that it is unnecessary to assume a "*proatlas*," as suggested by Albrecht,<sup>4</sup> because the vertebra supposed to be lost in the *amniota* is really present in the occiput. *Balfour's head-cavities* lie in front of the region studied by Frioriep, who considers their morphology as still problematic, and says "they can in no case be identified with *provertebrae*."

In his third paper Frioriep reaches a series of interesting results. He emphasizes especially that the ganglia of the facialis, glossopharyngeus, and vagus enter into intimate relations with the epidermis.

Opposite each ganglion the epidermis is thickened and partly invaginated; against this thickening the ganglion lies close, so that there is a close union between the ganglionic and epidermic cells, and the union may be so close that the line of demarcation between the two tissues cannot be determined. These structures are evidently to be interpreted as rudimentary sense-organs, but no trace of them is known to persist in adults. It is probable that they represent a portion of the series of so-called lateral organs, which in the lower vertebrates extend in a nearly continuous line, or series of lines, along each side of the body. But these organs in fishes and amphibia are connected with the dorsal branches of the nerves, while the rudimentary structures of mammals are connected with the ventral branches. The organs belonging to each of the three nerves, named above, are situated at the dorsal edge of the visceral cleft to which the nerve belongs.

The ganglion *nodosum* is supposed by Frioriep to correspond with several organs belonging to a number of visceral clefts, which in mammals no longer appear. Still more interesting is the striking resemblance which the acoustic nerve, with its ganglion and epidermal sensory apparatus, presents to the series of organs under consideration. This resemblance suggests at once the conclusion that the ear, that is, the membranous labyrinth, is really one of the series, and hence probably an extreme specialization of one of the sense-organs of the lateral line. These organs occur also in invertebrates, and were very likely developed as general sense-organs, and in the course of evolution the anterior ones became specialized to serve the auditory function. The question naturally suggests itself whether the eye and nose may not also be specialized members of the series of general sense-organs, which may be supposed to have extended originally along the side of the head and of the body. In the head region they have been much modified; in the body region they have been preserved in the lower vertebrates, but have disappeared in the *amniota*.

It will thus be seen that the whole problem of cephalic morphology has to be taken up *de novo*, for we have now to deal with a whole series of novel and complex problems, which lead us back far into the past history of vertebrate evolution, and put our inherited notions of the structure of the head out of count.

#### STRUCTURE OF EPITHELIUM.

A great change has occurred in our conception of relations of epithelial cells to one another. We now know that the adjacent cells are connected by intercellular bridges, or threads, of protoplasm, and that there are thus spaces between the cells. Into these spaces lymphoid cells may enter, and, according to recent researches, they do frequently so enter, sometimes in such crowds as to completely obscure the epithelium. This immigration appears to take place normally during digestion, and the lymphoid cells are believed to be active agents in the process of resorption. It is quite possible that the uterine decidua is similarly produced, lymphoid cells penetrating the uterine epithelium and becoming transformed into decidual cells. Peyer's patches are, perhaps, really epithelial structures permeated by lymph cells.

The extent to which such emigration may go is well shown by Stohr.<sup>5</sup> A great emigration of lymphoid cells through the epithelium takes place not only in the tonsils, but also in the sebaceous glands, in the solitary and conglomerate glands of the intestines, and the bronchial mucosa. The migrating cells shove themselves through between the epithelial cells; it does not appear that they enter the latter. The isolated epithelial cells appear much pressed in, and furnished with grooves, furrows, and notches; in some of the notches the lymph cells still are lying. If the migration is large the epithelium becomes so rarefied that it is pressed together into thin cords, or even becomes unrecognizable. At such spots the protecting epithelial covering is wanting, the tunica propria is freely exposed, which must be practically important; such spots Stohr designates as "physiologisch wunde." That injurious substances can act, and microorganisms penetrate, at these points more easily than elsewhere is probable. In fact, a group of small fungi sat in one preparation upon the surface of such a passage.

It is not easy to form any clear notion of the meaning of this normal and constant migration. Do the excreted elements play some rôle in digestion? Or is the object the removal of superfluous material? The migration does not appear to be connected with digestion, because numerous lymph cells are found even in starving animals. Against this view militates also the migration occurring in the vagina, bronchi, and conjunctiva. If the object is excretory it would be supposed that the migration would cease or be reduced during pregnancy and nursing. Yet in pregnant cats the migration was equal to that in the not pregnant. But in growing animals the migration is small. The author favors the excretory theory, but reserves decision for further research. Often the migrating cells appear to be disintegrating; it is possible that old, used-up lymph cells are thus removed. The structures considered are not to be confused with lymph glands proper.

How surprisingly large the intercellular spaces may become in epithelia has been demonstrated by Mitrophanow,<sup>6</sup> who has pointed out that the cells contract upon mechanical irritation, and in so doing magnify the spaces about them. The spaces are directly continuous with the lymphatic system, of which they constitute the ultimate rooflets.

From the sum of all the researches on this subject we gather for the first time an intelligible notion of the mechanism of absorption through epithelial surfaces. The lymphoid cells in the epithelial membranes seize the particles and pass with their prey directly into the lymphatics.

#### HISTOLOGY OF THE MAMMALIAN OVARY.

In an important article, W. Harz describes the cords of cells mentioned by various authors in the ovaries of some mammalia. The cords or canals grow out from the segmental canals of the Wolffian body into the ovary and toward the primitive ova; they must be considered homologous with the canals of like origin in the testis, a homology already established by Braun in the case of reptiles.<sup>7</sup> These

cords are developed to various extents in different species: they are wanting in man and the pig; they are found only in the hilus (sheep), or they may in bulk form the principal part of the ovary (Guinea-pigs, hare, *Cebus capucinus*, and horse), or they may be only the predominant tissue, as in the cat, cow, and Hapale. The cells of these cords find no analogy in other tissues, although they recall the liver cells in appearance. They take no part either in the formation of the granulosa layer around the ovum nor of the corpora lutea.

The ova arise in the epithelium and are overgrown by the neighboring epithelial cells, so that the ova are pushed down into the stroma of the ovary. The ova are not separated from the epithelium by the connective tissue growing in and forcing them apart, as Foulis has maintained. The immigration of ova continues until the tunica albuginea is formed; it is probable that this layer opposes an obstacle to the process. The oldest ova are found farthest from, the youngest nearest, the mesovarium, and the albuginea also develops last near the hilus. The granulosa is probably formed from cells of the stroma; it is certain that each *Urei* leaves the germinal epithelium without being accompanied by any other epithelial cells, such as have hitherto been generally believed to form the ovic envelope.<sup>8</sup>

#### NERVE TERMINATIONS IN THE HEART.

Openchowski, in a short article, gives a brief résumé of the numerous writings upon the nerves and ganglia of the vertebrate heart. He then reports his own researches, the most important points of which are: (1) In the heart of the frog, newt, and lizard throughout the muscles are very abundant nerve branches; (2) the medullated fibres of the vagi reach the "gründplexus" described by Gerlach, and there lose their sheaths at various heights; they accompany the Remak's fibres, but do not anastomose with them. The existence of the perimyscular net *anct.* cannot be maintained; (3) from the gründplexus the terminal fibres run directly to the muscles, where they end with little enlargements or terminal knots (Ranvier's "taches motrices"); (4) each muscle cell receives a knot; the nucleus of the cell has nothing to do with the nerve termination. Hence the heart, in respect of its innervation, may be regarded as composed of smooth muscles.<sup>9</sup>

### New Instruments.

#### THOMAS'S ANTEFLEXION PESSARY.

BY W. H. BAKER, M.D.

This instrument, which is the most efficient one for the majority of cases of antelexion of the uterus with which I am familiar, has sometimes annoyed me in two ways, namely, in a certain class of cases where there exists a shallow vagina; that is, where the vertical diameter of the vagina is very small there is a great liability of the joint or hinge cutting into the posterior wall of the vagina, on account of the irregular and somewhat unfinished end of such joint (see Fig. 1). In another class of cases the movable arm does not increase the

<sup>9</sup> Arch. mikros. anat., xxi, 408.

power, as is necessary in keeping the body of the uterus high enough to give the required relief.

To obviate these difficulties I have modified the instrument, which Messrs. Codman and Shurtleff have had made, so that the first objection is met by the joint itself becoming a part of the posterior

Fig. 1.

Fig. 2.

angle and finished regularly and smoothly with it, thus doing away entirely with the metal pin which supported the joint (see Fig. 2). The second difficulty is not only overcome, but the instrument made much more efficient by making the movable arm after the pattern of the lower part of an ordinary Albert Smith retroversion pessary.

## Reports of Societies.

### OHIO STATE MEDICAL SOCIETY.

ANNUAL meeting held at Dayton, June 3, 4, and 5, 1885.

Dr. C. D. PALMER, of Cincinnati, Professor of Gynecology, Medical College of Ohio, read a paper on

#### A RARE COMPLICATION AFTER OVARIOTOMY.

A young, delicate, unmarried woman, aged twenty-two, for three and a half years had an abdominal tumor. For this she consulted a number of physicians in succession, and was tapped, the diagnosis being ascites, eight different times. Her last attendant, Dr. John Kellar, suspecting that she was not suffering from ascites, asked Dr. Palmer to see the case with him. He diagnosed an unilocular ovarian cyst, which was confirmed by the operation. On the twelfth day a fecal fistula formed. This communicated inwardly with the lower small intestine, and the external opening presented midway between the umbilicus and symphysis pubis. At first it discharged several ounces of fecal matter daily. This has diminished gradually, until now, three months after the operation, it is only two to three drachms, and patient is steadily improving. Treatment has consisted only of diet and firm compress. Essayist thought that this fistula was caused by softening from the peritonitis. Spencer Wells found only one fecal fistula in his 1,000 published ovariotomies. Essayist wonders that such perforations, also lacerations, do not occur more frequently. He cited several cases gleaned from the literature. Considering the facts, he suggested the possibility that lacerations and perforations are of more frequent occurrence than supposed.

Dr. WM. MILLIKIN, of Hamilton, Lecturer on Medical Jurisprudence and Hygiene, Miami Medical College, read on

### EMPHYSEMA: ITS TREATMENT BY DAILY ASPIRATION THROUGH THE DRAINAGE-TUBE.

His plan was to make one small opening into the pleural cavity, and daily withdraw the accumulated pus by means of the aspirator. He injected then an amount of antiseptic fluid somewhat smaller than that he had withdrawn, giving the patient a feeling of discomfort for perhaps one hour. This he considered a movement cure. It gradually expanded the other well lung, contracted the chest, and allowed displacement of the mediastinal space toward the affected lung, thus giving the other more room for expansion. He claimed one hole in a man's chest to be better than two; a small one better than a large one; that free drainage would not draw pus out of a pocket, which the aspirator would. He reported two cases where he had used this plan quite successfully.

In the discussion which followed, Dr. P. S. CONNOR, of Cincinnati, thought both plans would fail; sometimes the one, then the other.

Dr. JOSEPH RANSOHOFF, of Cincinnati, had discarded the aspirator in emphysema. Early free incision, he thought, would save most cases. He reported a case of his where a drainage-tube was lost in the pleural cavity for fifteen days. Recovery of both tube and patient.

Dr. KINGMAN, of Columbus, spoke in favor of free incisions for emphysema. They should be made as soon as fluid is known to be purulent.

WM. T. CORBETT, M.D., L.R.C.P., London, Professor of Dermatology in the Wooster University, Cleveland, Ohio, read on

### DISEASES OF THE SKIN OF REFLEX NERVOUS CAUSATION.

He spoke of two distinct varieties of neurosis cutanea, one the senso-neurosis, in which the characteristic symptom is a disturbance of the sensation unaccompanied by any visible lesion. The second variety is the tropho-neurosis, which is characterized by anomalies of nutrition. Pruritus is a representative senso-neurosis and is a disease *sui generis* and not a mere accompaniment of cutaneous inflammation. Pruritus of the palms and soles is usually met with in females having some mild ailment of the uterus of long standing. Pruritus of the scalp, at times accompanied with a sense of weight, is met most frequently in women having a subinvolved uterus or a ruptured perineum. Pruritus vulvae unaccompanied by a vaginal discharge is a symptom of pregnancy; less frequently it precedes each menstrual flow. Adult males subject to constipation suffer severely from pruritus in the genito-anal region.

The reader then reported six interesting cases in a complete manner. In conclusion, he said:—

The most marked tropho-neuroses coming under his observation have closely simulated eczema. Unlike eczema, the eruption whether papular, vesicular, or squamous remains as such throughout its entire course.

Derangements of the sebaceous glands have been spoken of previously in this connection. Next to the eczematous group they are the most frequent.

Senso-neuroses, *arteris paribus*, are more fre-

quently associated with conditions of a mild nature, functional disturbances, nerve irritation, and the like, whereas tropho-neuroses, *cateris paribus*, more frequently accompany pathological conditions of a graver import, for example, nerve lesions or gross destructive changes in the cerebro-spinal substance, although we must admit that the latter also are not infrequently due to functional disturbance alone.

DR. R. HARVEY REED, of Mansfield, read on

#### VITILIGO.

This, he said, was a disease so rare, that Dr. McCall Anderson in an analysis of 11,000 cases found only four of vitiligo. This disease was most completely described by Duhring. Treatment in the essayist's hands had been very unsatisfactory. Under the supposition that it was of nervous origin he had given the hypophosphites. Friction, massage, electricity, and stimulating lotions had all had their trials. He hoped his paper would call attention to the subject and cause its elucidation. Until more light appeared, he would consider it a purely nervous disease, under protest.

DR. J. M. HIMES, of Cleveland, read on

#### MEDICAL EXAMINATIONS FOR LIFE INSURANCE.

The essayist desired in his paper to notice subjects not chosen because of special importance, but such as have an occasional or recurrent interest to those who have to do with life insurance. He considered:

- (1) Influence of life insurance upon the personal hygiene and the hygiene of cities.
- (2) Some conditions of doubt in examination of respiratory organs.
- (3) Some phenomena connected with the circulation of the blood.
- (4) The place where the examination is made.
- (5) Concerning the rejection of applicants.
- (6) Albumen in the urine.
- (7) Sugar in the urine.

P. S. CONNOR, M.D., LL.D., of Cincinnati, Professor of Surgical Anatomy and Clinical Surgery, Medical College of Ohio, Surgeon to the Good Samaritan and to the Cincinnati Hospitals, read a paper on

#### VESICAL EXPLORATIONS.

Morbid conditions of the bladder, said the essayist, may or may not be easily diagnosed. He thought endoscopic examinations, of which so much had been at one time expected, had proved to be of little value, though much more satisfactory in the female than in the male. The essayist then considered the various modes of vesical exploration, and said they should be supplemented by urinalysis, chemical and microscopical examinations.

Digital examinations, systematized by Sir Henry Thompson, afford information of the highest value. By the ordinary perineal section the membranous portion of the urethra is opened, the prostatic portion of the canal is dilated, and the finger is pushed into the bladder. By these means the finger can be brought into contact with every part of the bladder. The mucous surface can be palpated, its irregularities noted, the presence, location, size, and character of a concealed foreign body or stone in the lower portion of the urethra noted. In a recent case the bladder was as thoroughly explored as if

done postmortem. The objection is made that this is difficult in fat subjects, when the perineum is deep or the prostate enlarged. Yet in most cases the finger can be introduced into the bladder and made to sweep its walls. The operation is a simple one: merely the ordinary extra-perineal urethrotomy upon a grooved staff: and is almost devoid of danger. Guyon and certain other French surgeons advocate the supra-pubic operation rather than perineal section. The danger of the perineal section is not grave and the advantage of exploration much greater. For every reason, both for diagnosis and treatment, the digital exploration should always be made when the other more ordinary and longer-practised methods of examination have proved insufficient. In very young children lateral rather than median urethrotomy should be made, since such an operation does not increase the danger to life and relieves the surgeon of the trouble, at times quite considerable, of dilating the prostatic portion of the canal.

The discussion was introduced by DR. HOLLAND, who spoke of the rectal examination in a favorable manner. He used Sims's speculum of a large size. He regarded the perineal section, especially in private practice, for diagnostic purposes alone to be rather a bold procedure.

DR. RANSOUFF, of Cincinnati, spoke in favor of the operation, and reported a case in which he had made it. He also discussed rectal examination.

DR. CONNOR maintained that in many cases we are left entirely in the dark and cannot make a diagnosis. He has done this operation one hundred times, and in no case was death resultant from the operation. As for himself he would much rather be subjected to perineal section than be drugged, as many are. He has been much surprised to find with what ease the bladder can be explored.

DR. C. H. VON KLEIN, of Dayton, read on

#### VOICE IN SINGERS.

He first dwelt upon the beauty, power, and desirability of a fine voice. Then he went minutely into the anatomy, physiology, and hygiene of the voice. He considered the voices and singers of the majority of civilized nations, with especial reference to Italy. He discussed the reasons for Italy's superiority, and attributed it to the training rather than the air; also to the peculiar formation of the Italian's throat. He closed with a tribute to America's musical women.

DR. PHILLIP ZENNER, of Cincinnati, Lecturer on Nervous Diseases at the Medical College of Ohio, read a paper on

#### DISEASES OF THE SPINAL CORD.

The essayist's chief reason for bringing up this subject was the importance of the subject on account of the comparative frequency of these diseases, and the oftentimes difficulty in their diagnosis. Much of this failure to diagnose he thought to be due to the absence of the knowledge of the leading factors upon which a diagnosis is based. To prove this statement, and to bring the subject before the Society in a practicable manner, he reported four cases, selected from his casebook, in which errors of diagnosis had been made. He thought

that what was essential to the diagnosis of functional disease is that we should be able to exclude organic disease, and in all cases symptoms of this should be sought for. If a patient come to us with a history of pains, of weakness, of anomalous sensations pointing to the cord, we should examine as to the presence of ocular symptoms, as to the condition of the cutaneous sensibility of the tendon-reflexes, of the vegetative functions, especially bladder and rectum, and as to the kind of gait, to see if there are present any symptoms of locomotor ataxia; then if any motor paralysis, with increased tendon-reflexes and rigidity of muscles point to disease of the motor columns of the cord, or paralysis and atrophy of muscles, with altered electrical reaction point to affection of gray matter. If all such symptoms can be excluded we are probably in the presence of a functional disease. Such a diagnosis will bring immediate mental relief to an anxious sufferer.

DR. J. C. REEVE, of Dayton, in his official capacity, delivered the

#### PRESIDENT'S ADDRESS.

He spoke of the evolution of the science, now very imperfect; yet medicine compared very satisfactorily with law or theology. Medicine, said he, has always taken on the character of the age. It is to-day active, practical, and advancing. He would have been a bold man who at our last meeting, a year ago, would have said before we meet again ether and chloroform would be discarded as anesthetics in eye operations. He lamented the absence of a general theory of disease. He turned his attention to homeopathy. This sect has existed seventy-five years. In that time the regular profession has given to the world the stethoscope, ophthalmoscope, laryngoscope, chloral, ether, chloroform, cocaine, etc. etc. What has homeopathy given? Nothing.

#### THE SEVENTH ANNUAL MEETING OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

HELD AT DETROIT, JUNE 24-26, 1885.

The attendance at this session has been good, and the quality of the papers presented excellent. The congress was opened on Wednesday morning, June 24th, by an address of welcome from Dr. ENGEL, President of the Medical Library and Journal Association of Detroit. An address of welcome was also delivered by Dr. SHURLY, the President of the Association.

The first paper of the congress, also by Dr. SHURLY, of Detroit, was on

#### THE USE OF GALVANISM IN CHRONIC DISEASES OF THE PHARYNX.

In this Dr. Shurly stated that at the congress of 1880 he had called attention to the use of galvanism in a number of cases with good results. The difficulties attending the use of electrodes in the pharynx could be reduced through the use of cocaine, making this plan of treatment of general

practicability. He believed that certain conditions of the pharynx, such as chronic engorgement, hypersecretion, etc., are often only local expressions of a derangement of the stomach, the intestinal canal, or possibly some more remote organ. Certain neuroses of the pharynx, such as hyperæsthesia, spasm, also paræsthesia, are dependent upon derangement either of these same organs, or of the genito-urinary or mental apparatus, all of which require little or no local treatment. There were certain organic lesions, also, of the pharyngeal mucous membrane which were characterized by glandular hypertrophy, general hyperplasia, hypersecretion, atrophy with diminished secretion, etc. To these he wished to call special attention. They constituted changes which were trophic, and were distinct local disorders. He believed that glandular hypertrophy and atrophy, with or without persistent extra secretion, and with little organic change in the membrane, were due to a perversion of function of the nerve apparatus distributed through the pharyngeal region. Mere mechanical effect of infiltration or interstitial deposit could not account altogether for the waste of the membrane. It seems impossible, too, that the symptoms of typical pharyngeal disease could be fairly attributed to ordinary inflammation and its consequences. Some of these conditions were probably distinct local diseases, having for origin some nutritive abnormality antecedent to the inflammatory changes; perhaps due to metabolic derangement through a disordered trophic function of the hypoglossal, pneumogastric, or sympathetic nerve. Acting upon this theory, he had employed different agents for local use, and of these had gained more lasting effect from galvanism. The mucous membrane having remained in many cases of a vivid color, and bathed in a fluid secretion several hours after the application, and in case of atrophy leaving an exhilarating sensation of heat and pliability. In the severer forms of chronic nasal catarrh, in cases of engorgement with hypersecretion, and also in distinctly neurotic conditions, such as paræsthesia, he had had good effects from galvanism. The following method was advised: First, cleanse the membrane with some appropriate solution; then apply a four per cent. solution of cocaine, and in about five minutes apply the electrodes (which were then exhibited), one through the nasal passage and the other to the posterior and lateral wall of the pharynx, moving them rapidly, but gently, over the surface, and keeping them closely applied. He generally began with two cells, increasing to four or five, of a battery composed of the improved Leclanché cells. The electrodes are naked, unless one is to be applied to the side of the neck, when that is covered. The application should be repeated two or three times a week, although in some cases one thorough treatment a week is enough. This method will not restore already destroyed tissue, but it will arrest those metamorphoses which finally result in either the loss of glandular as well as other elements of the membrane, or the substitution of adventitious for the normal tissues. The time required for permanent results will vary with the case and the state of chronicity presented. The only therapeutic theory was the restoration of the nutrition and normal secre-

tion of the parts by the direct application of the electrical fluid to the terminal nerve filaments.

DR. F. H. HOOPER, of Boston, next read a paper entitled

THE RESPIRATORY FUNCTION OF THE HUMAN LARYNX,  
FROM EXPERIMENTAL STUDIES IN THE PHYSIOLOGICAL  
LABORATORY OF HARVARD UNIVERSITY.

The reader doubted the accuracy of the theory which had been advanced by many writers that there was a proclivity of the abductor fibres of the recurrent pharyngeal nerve to become affected by disease earlier than the adductor fibres, and his paper was an inquiry into the truth of this problem solely from an anatomical, physiological, and experimental standpoint. The sources from which nervous impulses for the larynx could be received, and the channels through which they might be transmitted, were minutely reviewed, and the conclusion was reached that the respiratory, or abductor, nerve filaments contained in the recurrent laryngeal were derived from a greater variety of sources than the phonatory, or adductor, fibres. The respiratory muscles of the larynx were physiologically more important than the other intrinsic laryngeal muscles, and their extensive nerve-supply, the reader claimed, was to protect them from disease, not to open up new channels by which harm might come to them. The experiments were performed on dogs and, on one occasion, a horse. The dogs were so arranged that the vocal bands could be watched through the mouth while the recurrent nerves were stimulated. It is a familiar fact that under normal conditions any irritation applied to one or both of the recurrent nerves produces a sudden closure of the glottis. The experiments were made on dogs: first in a state of profound narcosis; second, by irritating the recurrent nerve while it is being slowly destroyed by crystals of chromic acid placed upon it; third, after a thread had been passed through the nerve, and retained there many days in order to excite inflammatory changes. The reader found that when a dog is profoundly etherized the action of the constrictor muscles of the glottis is completely abolished. Under these circumstances any stimulation applied to the recurrent nerves produces a forcible dilatation of the glottis instead of the familiar closure. The experiments with chromic acid did not show that there was a proclivity of the abductor fibres to succumb earlier than any others. In one experiment in which a thread had been inserted in the recurrent nerve and kept there a week, it produced some alteration of the nerve fibres, so that when the nerve was irritated below this point the vocal band was abducted, showing that the adductor fibres had lost their power to respond to stimulation. The conclusions were as follows: The principal fact demonstrated was the power and endurance of the posterior crico-arytenoid muscles and of the nerves which supply them. The theoretical reasons were: first, the physiological importance of these muscles; second, their belonging to organic life; third, their extensive nerve-supply, all of which would tend to preserve their functional integrity. Moreover, if it were true that there was a "proclivity" of the abductor fibres to become diseased, and that imilate-

ral paralysis of the abductor muscle is such a common and harmless lesion, could we not expect theoretically that bilateral paralysis of this muscle would occur more frequently? Yet there could be no dispute whatever that bilateral paralysis of the posterior crico-arytenoid was a disease as rare as it was grave. Now with regard to these muscles being *extensors*, and like the extensors in other parts of the body, the forearm for instance, more liable to succumb to disease than the flexors, he would ask this simple question: Why should the term extension and flexion be applied to the rotation of the arytenoid cartilages?

The principal office of the posterior arytenoids is to maintain the respiratory patency of the glottis. From the beginning to the end of life they are in a state of semi-contraction. They came, therefore, just as near being flexors as extensors; but, as a matter of fact, were neither the one nor the other in the ordinary acceptance of these terms as applied to the muscles of the general system. They were respiratory muscles carrying on a special function. One might as well speak of the movement of the pupil as extension and flexion, or compare the diastole of the heart to the extensors of the forearm, or its systole to the bending of the toe. Muscles are analogous as they discharge analogous functions. We recognize no more analogy between the posterior crico-arytenoid muscles of the larynx and the extensor communis digitorum of the forearm than there is between respiration and prehension. If it were desired to seek muscles that were analogous, other respiratory muscles should be examined and the influence of disease upon them noted. In diffused progressive diseases of the neuro-muscular system it was known that of all muscles, except the heart itself, those belonging to the respiratory system were always the last to be attacked, and there was no valid reason why the respiratory muscles of the larynx, either one or both, should offer an exception to the rule, especially as they were the most important of all. The writer proposed to investigate this subject from a clinical aspect at some future date, when perhaps the positions which immobile vocal bands assume might be sufficiently explained without attributing to a wise and conservative nature a proclivity to attack one of the most vital muscles of the human system.

DISCUSSION.

DR. J. SOLIS-COMEN considered it a great honor to the American Laryngological Association to have had this valuable paper brought before it, and believed it would be historical. These experiments would be subjected to criticism, and their verification would become a matter of history in the controversy now existing as to the peculiarity of these abductor fibres to become diseased sooner than the adductors. The dogmatism with which the assertion had been made seemed to have almost paralyzed laryngologists; for, with the exception of himself, he hardly knew any one who had ventured a word against it. Even when he had presented a clinical case opposing the theory, and had showed a picture of a larynx, it had been simply in deference to himself that much had not been said against it. The only word of com-

mentation he had received was from Dr. Krause, of Berlin, who had stated that he believed the observation was correct; but attributed the lesion to a different cause. He had had no experience in the physiological experiments made by Dr. Hooper; but there was a point which the latter mentioned which had received clinical support. It was with reference to the facial nerve in sending the respiratory forces to the laryngeal. In the case of a child suffering from diphtheria with great dyspnea he declined to perform tracheotomy because the child was under two years of age. Knowing the great effect of cold on the facial nerve in stimulating the facial centres he placed iced cloths all over the lower part of the neck and jaw. Whenever the iced cloth was applied an inspiration took place. By repeating this frequently the child's life was saved. The phenomena in stimulating one recurrent so that its vocal band passes beyond the median line as in phonation was confirmatory of some of Krause's experiments.

Dr. HARRISON ALLEN, of Philadelphia, said the analogy between constriction and adduction and between dilatation and abduction was in his judgment tenable.

Dr. INGALLS, of Chicago, said that, in support of the paper, in a clinical way he had recently had a case similar to the one related by Dr. Cohen, excepting as to the origin.

Dr. DELAVAN, of New York, desired to unite his congratulations to those of Dr. Cohen, upon Dr. Hooper's paper. Reference had been made in the paper to a motor centre for the human larynx. Since publishing his own paper on this subject, several important contributions had appeared, which tended still further to establish the fact of the existence of such a centre; and he hoped that sufficient clinical evidence would soon be accumulated to place the matter beyond a doubt.

Dr. HOOPER, in closing, stated that he had only attempted in his paper to study the subject on general physiological and experimental grounds. Clinically, it seemed a difficult question, and one in which there were many sources of error. We were dealing with one of the most complicated organs in the body, and in using the laryngeal mirror were looking at things in perspective which were in almost constant motion. It is often impossible to say whether a vocal band stands motionless in the median line or a few millimetres from it. If we call every paralyzed vocal band we see a paralysis of the posterior crico-arytenoid muscle we can multiply such cases very rapidly. The theory that there is a "proclivity" of the posterior crico-arytenoid fibres to become diseased is not only contrary to nature, but the dogmatic manner in which it has by some been advanced ought of itself to cause us to doubt its accuracy. He would feel sorry to have an association like our own subscribe to this notion on the very shallow evidence at present presented. The speaker desired to express his indebtedness to Dr. Bowditch, professor of Physiology of the Harvard Medical School, and others connected with the department, whose assistance had been of value to him in the preparation of his paper.

Dr. H. A. JOHNSON, of Chicago, next read a paper on

#### SOME OF THE MOTOR DERANGEMENTS OF THE LARYNX, WITH CASES.

in which he related the histories of over twenty cases, of unusual interest and value.

Dr. WILLIAM C. GLASGOW, of St. Louis, next presented a paper on

#### CERTAIN VASO-MOTOR DISTURBANCES OF THE NASAL MEMBRANE.

He stated that for some time his attention had been attracted by a series of cases which were not explained by the well-known factors in inflammatory process; though resembling them somewhat, there were still differences which necessitated an additional and independent influence for their production. The laws of vaso-motor action, although still imperfectly developed, would seem to explain them; and the success attending the use of therapeutic agents to verify it. The observations of the writer had led him to arrive at somewhat different views than those developed by several members of this society, especially by Drs. Mackenzie, of Baltimore, Roe and Daly, and by our co-laborer Haack, of Freyburg. He had noticed a series of cases characterized by great swelling, especially of the cavernous tissue, and a profuse discharge of lymphoid fluid and abnormal paleness of the mucous membrane. Formerly, when they occurred during the summer months, he had been content to consider them as modified types of so-called hay fever; occurring during the year, irrespective of seasons, he had become convinced that there was a different agency from that then recognized as the essential factor in hay fever. He believed that the chief half of the disturbance was neurotic, considering the so-called hay fever to be a functional disorder of the nervous system, in which hypersensitiveness of the nasal mucous membrane occurs, producing there the well-known reflex symptoms and disturbances of the normal vaso-motor action; he still considers those cases as closely allied both in etiology and mechanism with the so-called cases of hay fever. He had selected three cases which showed the distinct and different types of nasal disturbance. The writer concluded that the condition was due to contraction of the arterioles due to an increased tone of the vessels, caused by an augmented action of the constrictors. In short, the minute vessels supplying the arteries were in a state of spasm and dilatation. The general arterial tension was increased, the outward flow of the more solid portions of the blood was prevented, and the cavernous bodies of the mucous membrane became infiltrated with escaping white corpuscles and the liquor sanguinis. To those must be added the liquefaction and the increase of the glandular secretions as the result of gland stimulation. The theory of spasm of the arterioles was supported by the favorable action of remedies which favor arterial dilatation — such as atropine.

The discussion was participated in by Drs. Roe, Robertson, Mackenzie, and Allen.

Dr. JOHN N. MACKENZIE, of Baltimore, read a paper on

#### THE ETIOLOGY OF THE SIMPLE INFLAMMATORY AFFECTIONS OF THE UPPER AIR-PASSAGES.

His conclusions were as follows: First, inflamma-

tion of the upper respiratory tract, either in its entirety, or localized in its individual parts, is a disease of the human race, which has existed from the remotest period of historic times. Second, as the chief predisposing and exciting causes of the affection have been in operation for all ages, its origin is, therefore, coëval with the birth of man. Third, the evolution of nasal, pharyngeal, and laryngeal disease in a given locality is in all probability a part of its geological history, and goes on *pari passu* with its varying meteorological conditions. Hence the geographical limits of the disease have varied with different epochs of the earth's formation.

The first portion of Dr. MacKenzie's paper was devoted to the elaboration of the above propositions. He next discussed in detail the chief predisposing and exciting causes proceeding from affections of the system as a whole, or disease of individual organs remote from the nasal passages, and the relations of syphilis, tuberculosis, gout, rheumatism, etc., to the affections in question. Having shown that nasal and laryngeal disease may proceed from a direct or indirect irritation, from a host of substances derived from the outer world, from an almost indefinite number of pathological conditions of the body as a whole, or from irritation or disease of organs distant from the seat of local inflammation, the reader proceeded to the discussion of the part which structural peculiarities play in the etiology of these affections, and to the consideration of the so-called catarrhal diathesis, which latter might be looked upon simply as a generic term for a multitude of varied physical peculiarities. Setting aside the inflammation which results from purely local irritation it might be laid down as a law that the vast majority of catarrhal, pharyngeal, and laryngeal disease originate primarily in inflammation of the nasal cavities. He next quoted a number of causes efficient in the production of catarrh, and closed his paper with a proposition that in a large proportion of cases the existence of chronic inflammation in the nasal, pharyngeal, or laryngeal cavities was not due to any one particular cause but was the resultant of a number of internal and external forces.

#### DISCUSSION.

Dr. CONN remarked that the climatic conditions referred to in the paper often could not be altered. The patient, however, could be protected by suitable hygienic and dietetic supervision. The functions of digestion and excretion must be attended to, the skin be kept in good order, and thus revulsive measures be adopted to withdraw morbid influences from the upper respiratory tract. Local measures without due consideration of constitutional conditions did not fulfil the requirements. Acute laryngitis occurred frequently in those not suffering with chronic catarrhal disease and subsided without such a sequel. On the other hand subacute inflammations had occurred most frequently in his experience in the subjects of chronic disease as exacerbations due to some special exposure. The spasmodic affections of infants alluded to in the paper as occurring in the subject of chronic naso-pharyngeal catarrh were similar in origin to the night-cough of infants, being due to tickling of mucous into the larynx.

The indication, then, is to place the sleeping infant in a position which will not allow the entrance of secretion into the larynx and of course to treat the catarrhal disease.

Dr. H. A. JOHNSON, of Chicago, remarked that naso-pharyngeal catarrh was common around our great lakes, and was frequently benefited by a change of climate to the Western plains up to an altitude of five or six thousand feet. In high mountains the disease was aggravated. General tonics are of great value.

Dr. INGALLS, of Chicago, also emphasized the necessity of attention to the constitutional condition, but said, on the other hand, we should not lose sight of the constitutional manifestations due to the nasal disease. In many cases great impairment of general health is dependent upon nasal obstruction, and remarkable improvement would immediately succeed removal of the nasal obstruction.

Dr. GLASGOW, of St. Louis, believed that dust held a most important place in the production of catarrhal symptoms.

Dr. ALLEN considered that local treatment in these cases was of great importance.

Dr. MACKENZIE closed the discussion by stating that his position was that the localization of catarrhal processes in the retro-nasal space or the geographical limits of the disease have little to do with the presence of dust in the atmosphere. While it was true that dust accidentally lodged in the nasal passage might give rise to inflammation, he believed that few cases originate in this way, for reasons which he had explained in his paper.

Dr. D. BRYSON DELAVAN next read a paper on

#### ERYSIPELAS OF THE LARYNX AND PHARYNX.

The reader referred to the classic thesis upon this subject, published by Cornil, in 1862, and stated that although well-known to Hippocrates the subject had of late received so little attention, particularly in this country, that but one case had been reported, while Morrell Mackenzie stated in his *résumé* of it that he had seen but four. Having given a short review of the subject, the writer proceeded to relate two original cases. In the first the disease originated in one tonsil. It spread over the pharynx and thence extended through the nasal cavities to the lips, face, and head. The patient suffered from marked cerebral symptoms of an acute form and two weeks after convalescence developed a condition of insanity which remained chronic. The next case occurred in an aged patient of rheumatic habit and broken-down constitution. She was attacked with what at first seemed acute laryngitis. The disease, however, spread in both directions involving both the lungs and the pharynx, producing in the former distinct and widespread broncho-pneumonia and in the latter an intense congestion. Laryngoscopic examination showed the larynx to be tumefied and of a dark-purplish color. There was no necessity for tracheotomy, however. The constitutional symptoms were comparatively slight. The patient recovered. The cerebral symptoms in case first were evidently due to an acute meningitis due to the influence of the systemic poisoning. This having become chronic was the cause of

the resultant insanity. The writer believed that erysipelas of the pharynx and larynx was not an uncommon affection, and urged that greater interest be taken in the recognition and recording of cases.

DR. DEBLOIS, of Boston, called attention to a case of this kind which he reported about a year ago.

DR. RICE, of New York, agreed with the writer in believing the disease of occasional occurrence among the broken-down subjects met with in general hospital practice.

DR. ROE, of Rochester, had in a similar case applied a spray of alcohol with good success.

DR. COHEN suggested that from the well-known efficacy of the hydrochlorate of pilocarpin in facial erysipelas it might prove a valuable remedy in this special manifestation.

DR. DELAVAN, in closing the discussion, suggested that in the use of pilocarpin the dose commonly recommended was excessive. He had made an extended series of observations upon the effect of this drug, and believed that the dose of one twentieth of a grain hypodermically should, as a rule, be the maximum when administered to a patient for the first time.

In the course of the business meeting which followed next in order the report of the librarian excited much interest. During the last six months the library had been more than doubled, and the catalogue presented by the librarian showed a list of 25 bound volumes and 364 pamphlets. The support of the Association and of its friends was earnestly solicited.

(To be continued.)

## Recent Literature.

*A Manual of Bandaging.* By C. HENRI LEONARD, A.M., M.D. Detroit: Illustrated Medical Journal Co. 1884. Second edition.

This edition of Dr. Leonard's Manual contains nearly thirty more pages than the previous one. The most important addition is the chapter on Immoveable Dressings.

The book contains much instruction for the student making his first acquaintance with the art of bandaging, and the one hundred and thirty-nine engravings, while not artistically beautiful, are useful in assisting to an understanding of the text.

*Operative Surgery.* By K. McLEOD, A.M., M.D. London: J. A. Churchill. 1885.

The title of this book might be misleading. It is a pretty full report of all the surgical cases treated by Dr. McLeod in a service of five years at the Calcutta Medical College Hospital, and would be of especial interest to the collector of statistics. One cannot but feel sorry that the author did not give the results of his experience in a concise form, more attractive to the general reader. The matter upon the radical cure of hernia is of especial interest.

## Medical and Surgical Journal.

THURSDAY, JULY 9, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### THE WORK OF THE NEW COMMITTEE AND THE ORGANIZATION OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

A MEETING of the new committee on the organization of the Ninth International Medical Congress, appointed by the American Medical Association at New Orleans, was held in Chicago on June 21st and 25th. Twenty-eight of the forty-five members were present. Sufficiently satisfactory assurances as to the legality of the new committee — among others, that of a former speaker of the National House of Representatives, Hon. S. J. Randall — had been obtained to secure the attendance and participation of several members of the original committee of seven.

The committee did the work expected of it, and with less malice than would have been possible, but with sufficient thoroughness, we fear, to put an end to the prospects of a successful and creditable international congress, and adjourned to meet in St. Louis on the first Monday in May, 1886. The rules were amended so as to confine membership to the constituency of the American Medical Association. The American members, it is decreed, shall consist of delegates from the American Medical Association, and from medical societies in affiliation with it, each of these societies being entitled to one delegate for every ten members. The number of sections was reduced from nineteen to sixteen, and the presidents of sections are no longer *ex officio* members of the General Committee.

Dr. H. I. Bowditch, of Boston, was dropped from the list of vice-presidents, Dr. A. Jacobi from the presidency of the Section of Diseases of Children, Dr. Lefferts from that of Laryngology, Dr. H. P. Bowditch from that of Medical Education, and Dr. H. D. Noyes from that of Ophthalmology. Numerous changes and additions were made in the vice-presidents and members of council of the different sections. These honors are issued as plentifully as fiat money after a *coup d'état*, and the various geographical divisions of the country are impartially besprinkled with them. A publication of the full list would require much space; and, as

this is already the second long list made public within a few months, as the refusal by many prominent men to serve as officers under existing conditions makes certain the appearance of other revised lists, which may eventually end in no list at all, we content ourselves with referring our readers to our news columns for the present organization of the Congress and for changes in the presidents and vice-presidents of sections. In the same columns will also be found a report of the action of prominent physicians in Philadelphia and Boston connected with the organization of the Congress. These refusals to accept office in the present organization will doubtless be followed by others.

These gentlemen proposed to aid and participate in the discussion of questions of medical science, not of medical ethics, medical politics, or of square miles of territory. There will, however, be more offices, although less congress, for those who prefer such discussions and such distinctions to a harmonious gathering of scientific men searching for truth; and we hope somebody may be happy, if it be only for a short time.

#### THE TREATMENT OF SPINA BIFIDA.

As abstract of the report of the committee<sup>1</sup> appointed by the Clinical Society of London, to investigate the treatment of spina bifida, by the injection of a solution of iodine in glycerin, has recently appeared.

We are presented with the deductions of a committee who have been over two years in collecting their information, and these are certainly of great practical interest.

They conclude that there is an absence, in the walls of the tumor, of the meso-blastic tissues; and practically accept Morgagni's theory that the deformity is due to a lack of development of this embryonic tissue. From microscopical sections they conclude that the fissure does not include the cord, for the central canal of the cord has been demonstrated in the expanded tissues of the walls of the sac. In the common lumbosacral spina bifida they find that ordinarily the spinal cord is flattened out and blended with the wall of the sac, especially in its posterior median, vertical portion, and the nerves are not distributed to the walls of the sac as ordinarily supposed.

How the radical measures which have been advanced for the treatment of this deformity have met with any measure of success is indeed a question of much interest. In the majority of cases the elements of the spinal cord are distributed and make a part of the wall of the sac.<sup>2</sup> Now if we

ligature the tumor, with or without subsequent excision of the sac (Paget, Erichsen, Whitehead); or completely extirpate the sac and close by sutures (Dubourg, Tavignot, Mayo Robson); or clamp the tumor and remove (Pye),<sup>3</sup> we probably should remove, at least in many cases, a section of the spinal cord or the cauda equina. This would naturally be considered a heroic measure.

On the other hand, many cases are recorded of success where the tumor has been excised with antiseptic precautions.

The committee, however, express themselves in no uncertain terms; they discountenance any radical operation that proposes the removal of the sac or the median vertical portion, into which the cord is ordinarily inserted; and are agreed that the treatment by injection of Morton's solution is by all odds the safest:—

R	Iodin, pur.	gts. x
	Potass iodidi	gts. xxx
	Glycerine	℥i.

Professor Humphrey,<sup>4</sup> in a valuable lecture recently delivered, arrives at nearly the same pathological conclusions as the committee. He emphasizes the following points: that the cord is commonly attached to the posterior wall of the sac of the tumor; and that the sac is most frequently formed from the subarachnoid space, thus being shut off from the dangerous arachnoid cavity.

With our present knowledge of this subject it would seem that surgeons should content themselves with the milder methods of treatment; as

(a) (1) Protection of the tumor by shields. (2) Simple compression without puncture. (Cooper. Heister.)

(b) (1) Puncturing the tumor with a thin antiseptically clean trocar; partial evacuation of fluid followed by light compression, or frequent aspirations. There is frequently much trouble in controlling the oozing from the cyst after puncture. (2) Painting with collodion. (Behrend reports a case cured.) (3) Puncturing followed by the injection of iodine (Brainard, Velpeau, Chassagnac). (4) The injection of a half-drachm of Morton's fluid, without allowing the fluid to escape, at intervals of from a week to ten days. Morton reported in his monograph, we believe, over fifty per cent. of cures.

The committee consider hydrocephalus, marasmus, paralysis, the presence of an impulse between the tumor and the anterior fontanelle, or a thin-walled ulcerated sac, as contraindications to operative interference.

As the committee suggest, a lack of discrimination in reference to the selection of suitable cases for operation undoubtedly accounts for the mortality recorded.

The committee advise non-interference in infants

<sup>1</sup> British Medical Journal, May 30, 1885, p. 1698. The committee consisted of Mr. Howard Marsh, Mr. Pearce Gould, Mr. H. H. Clutton, and Mr. R. W. Parker.

<sup>2</sup> Mr. R. W. Parker stated in a discussion at the Clinical Society, March 27, 1885, that, in ninety-five per cent. of the cases of spina bifida, the sac contained nerve tissue.

<sup>3</sup> Pye's case recovered; there were no nervous structures in the wall of the sac.

<sup>4</sup> Lancet, March 28, 1885, p. 557.

under two months of age. Certainly, at any age we think that, if it be possible to properly protect the tumor against danger, it is wise not to interfere.

A certain number of cases come to the surgeon in which it is a matter of necessity to adopt some operative procedure; and it is important to recognize the fact that it is impossible to diagnosticate the presence of the cord or any of the nervous elements in the sac. It is commonly thought that the presence of especial tenderness or the onset of convulsions from manipulating the sac is evidence of the presence of the cord. Hofmokl<sup>5</sup> records a case when he could grasp the cord in a spina bifida without producing either pain or convulsions.

The committee have carefully avoided generalizations from individual experiences, and have broadly grasped the whole subject of the operative treatment of spina bifida. The subject is one of great interest; and we regret that the committee have not published their report in full. However, they have tersely given us their conclusions; and we await with interest the appearance of the detailed report, which will appear in the annual Transactions of the Clinical Society.

#### THALLIN: ANOTHER NEW ANTIPYRETIC.

We are indebted to the industry of Continental chemists for still another antipyretic obtained by way of synthesis. It is a derivative of quinoline, and is called *thallin* from the emerald-green color which characterizes its solution when treated with bichromate of potash, perchloride of iron, and various other reagents. The original German name of this substance is *tetrahydroparamethylorquinoline*, or, as some would have it (heaven defend us from such chemical nomenclature!), *tetrahydroparamethylnisol*;  $C_{10}H_9NO$ .

Thallin was discovered by Skraup in 1881, and has been made the subject of clinical experimentation by Professors Nothnagel and Jacksch.

The two salts of thallin which have been principally utilized in medicine are the sulphate and tartrate, which present themselves under the form of a white crystalline powder, with slightly bitterish saline taste. The tartrate is soluble in ten times, the sulphate in five times, its weight of water.

It has been shown that the sulphate is more active than the tartrate; and this is the salt which Jacksch has used and with which he has made trials in cases of typhoid fever, rheumatism, erysipelas, measles, puerperal fever, pneumonia, and tuberculosis. Like antipyrine, thallin is said to have no effect in intermittent fever. It is an antithermic and not an antiperiodic. Its febrifuge properties are manifested in the human subject in doses of from three to fifteen grains and given to the extent of from twenty to forty grains a day.

From the communication to the Société de Thérapeutique of M. Henri Huchard, we learn that the salts of thallin produce after their administration slight chills, then profuse sweating, attended with nausea, a possible result of their disagreeable taste; but they do not provoke cyanosis, collapse, or phenomena of adynamia; nor has M. Huchard witnessed the appearance of methemoglobin in the blood which other experimenters have signalized. The thermic fall lasts four or five hours, but the secondary ascension of the temperature is marked by chills. Sometimes abundant sweats are observed a quarter or a half an hour after the administration of the medicament.

Thallin also possesses antiseptic properties. A twenty per cent. solution arrests the ammoniacal and alcoholic fermentations.

Huchard's experience with thallin assigns to this new medicament an antipyretic rôle much inferior to that possessed by antipyrine, its action being less sure, less marked, and less enduring.

Grocco, of Pavia, has also experimented with thallin, and he has arrived at the same results: gastric tolerance, chills and sweats, heat fall of one or two degrees in hyperpyrexia, no efficacy in intermittent fever. While the temperature falls the pulse diminishes somewhat in frequency; the diaphoresis is almost as abundant as that which follows the administration of *jaborandi*. Huchard, in explaining the *modus operandi* of thallin in lowering febrile temperature, ventures the opinion that it acts by augmenting the radiation of heat through the dilatation which it effects in the peripheral vessels, and that it exercises no influence on the febrile process itself; that is, it affects the vaso-motor, not the thermogenetic, centres.

The conclusions of Huchard do not agree with those of Brouardel and Loye, who, after repeated experiments on animals, have found thallin to be a dangerous medicament, changing hæmoglobin into methemoglobin, and thus diminishing the oxidizing power of the blood and arresting the organic combustions.

These experimenters have constantly noted, after the administration of thallin to animals, the presence of methemoglobin in the blood, and the animals die as if profoundly anæmiated by hæmorrhage. The phenomena of asphyxia are very marked.

Dujardin-Beaumetz has experimented with thallin in two cases and has observed profuse sweats and depression of the temperature. He classes thallin along with kairin among antipyretic medicaments which diminish the respiratory power of the blood.

This writer, in the last edition of his "Leçons de Clinique Thérapeutique," divides antithermics into three groups: those which mechanically abstract heat, and of which the cold bath is the type; those which act on the thermogenetic centres, the types of which are quinine, antipyrine, and salicylic acid; and those which diminish the respiratory (oxidizing)

<sup>5</sup> Medizinische Jahrbücher und Anzeiger, 1875. \*1 hier das Wesen und die Behandlung der Spina bifida," p. 143.

capacity of the blood, in which class, as before said, he ranges kairin and thallin; the latter being, in his opinion, dangerous medicaments which ought to be banished from therapeutics.

M. Huchard, who is disposed to regard this new medicine with greater favor, would restrict its use to certain cases of tuberculous fever, or of ordinary fever when the hyperpyrexia is intense. Sulphate of quinine and salicylic acid, in acting on the febrile process itself, and restraining heat production, possess, he thinks, a marked superiority as antithermics over thallin. According to this authority, salicylic acid and salicylate of soda are contraindicated in febrile pulmonary affections and especially phthisis, as they tend to produce congestions on the part of the lungs. Huchard furthermore insists that in clinical medicine there are no *antithermics*, but rather *antihyperthermics*; the indication to employ the powerful heat-depressants existing only when the pyrexia is excessive and a source of danger.

#### MEDICAL NOTES.

—The conviction of Pel, the Parisian murderer, was secured in the absence of discovery of his victim's body, which, of course, involved much additional labor on the part of those who conducted the case for the prosecution. The murdered woman, Pel's mistress, was found by two neighbors ill with persistent vomiting. After a few days they were refused admission to see her; and a week after the last time they saw her they were informed by Pel that she had left him without saying whither she was going. She was never seen again. During those days it was noted that Pel was keeping up a large fire in his stove, and an offensive odor was perceived in the neighborhood. Among the experiments performed by the medico-legal advisers of the prosecution was the burning of a human body in a small stove in the morgue, in order to demonstrate that it could be so thoroughly destroyed as to leave no traces behind. There was evidence that the lethal agent employed was arsenic, which Pel seems to have used on more than one occasion. The same poison was found in the body of his wife, who died four years before; but he claimed that she had been taking Fowler's solution as a medicine, and the jury failed to convict on that charge.

M. Vulpian has recently shown, says the Paris correspondent of the *British Medical Journal*, after having determined what is the minimum electric stimulus necessary to apply to the gray substance of the brain in order to provoke movements, that the same effects are obtained by a weaker current, if isolated electrodes (entirely covered by gutta-percha, except at the extremity) be allowed to penetrate the gray substance until they reach the white matter. He also affirms that epileptic attacks are provoked by stimulating the underlying white

bundles by weaker currents of less duration than those used for stimulating the surface of the gray substance. Other experiments by M. Vulpian tend to show that the gray cortical substance is of quite secondary importance in the pathogeny of epilepsy. M. Vulpian has arrived at this conclusion from freezing the cerebral surface of a dog by methyl-chloride, and then applying an electrical stimulus, which provokes epilepsy. The results of his researches appear to be opposed to the doctrine of functional cerebral localization. They indicate that the nerve-fibres destined to transmit cerebral motor initiations from certain regions to a limb, for example, may issue from a certain circumscribed area without the superposed gray substance being necessarily a defined initiating area. M. Vulpian, in the course of his experiments, observed that in less than a minute after the last heart-beat, faradization of neither the gray nor white cerebral substance provoked the slightest movement of either the limbs or the face. This demonstrates that, among the higher order of mammals, the cerebral substance loses its motor stimulus as soon as the circulation is arrested in the nerve-centres.

—A Sanitarium at Virginia Water, England, the gift of the late Mr. Holloway, the well-known pill-maker, was recently opened by the Prince of Wales. It is designed for the treatment of the curably insane of the middle classes, and is intended to be self-supporting. It will accommodate two hundred patients, and stands in grounds of some thirty-two acres in extent. The buildings are richly furnished, and appear to contain whatever is most useful for their purpose. The grounds are also tastefully laid out. Dr. Sutherland Rees Philipps has been appointed medical superintendent.

—The following test for oleomargarine is given by the *Therapeutic Gazette* as at once reliable and simple. A few drops of sulphuric acid when placed on genuine butter produce first a yellowish-white and after ten minutes a brick color, while oleomargarine treated in the same manner assumes first an amber and later a crimson color.

#### Miscellany.

#### THE LATEST ORGANIZATION AND CHANGES IN OFFICERS OF SECTIONS OF THE PROPOSED NINTH INTERNATIONAL MEDICAL CONGRESS.

The new Committee of the American Medical Association appointed the following organization and presidents and vice-president of sections for the proposed Ninth International Medical Congress:—

Dr. Austin Flint was retained as President. Dr. Henry I. Bowditch, of Boston, was stricken from the list of Vice-presidents, and there were added Drs. John L. Atlee, of Lancaster, Pa.; O. W. Holmes, of Boston; W. O. Baldwin, of Mont-

gomery, Ala.; J. M. Toner, of Washington; Wm. Brodie, of Detroit; L. A. Sayre, of New York; W. W. Dawson, of Cincinnati, and H. H. Skillman, of Lexington, Ky.

Dr. John H. Packard, of Philadelphia, was elected Secretary-general, and Dr. F. S. Dennis, Chairman of the Finance Committee.

The Executive Committee was constituted as follows: Drs. Beverly Cole, of California, Chairman; J. V. Shoemaker, of Philadelphia; A. Y. P. Garnett, of Washington; J. H. Packard, of Philadelphia; F. S. Dennis, of New York; J. S. Lynch, of Baltimore; J. W. S. Gouley, of New York; William Pierson, of Orange, N. J.; Christopher Johnston, of Baltimore, and J. C. Tucker, of Alameda, California.

A Local Committee of Arrangements was also appointed, consisting of Dr. A. Y. P. Garnett, of Washington, Chairman, and all of the Washington members of the Committee and of the Councils of the Sections.

In the Section of Medical Education, Legislation, and Registration, Dr. S. E. Chaillé, of New Orleans, displaced Dr. H. P. Bowditch, of Boston, as President, and Drs. George Cupples, of Texas, and R. J. Dunglison, of Philadelphia, were substituted as Vice-presidents for Drs. Chaillé and Stillé, of Philadelphia.

In the Section of Anatomy Dr. C. W. Kelly, of Louisville, and Dr. W. H. Pancoast, of Philadelphia, were added as Vice-presidents.

In the Section of Physiology, Dr. H. P. Bowditch, of Boston, was added as a Vice-president.

In the Section of Medicine, to which that of Nervous and Mental Disease was added, Drs. Alonzo Clark, of New York, S. Weir Mitchell, of Philadelphia, and P. G. Robinson, of St. Louis, were added as Vice-presidents.

In the Section of Surgery, Dr. Moses Gunn, of Chicago, was added as a Vice-president.

The Sections of Obstetrics and Gynecology were united, and Dr. Battey, of Rome, Ga., made President, and Drs. T. A. Reamy, of Cincinnati, John Goodman, of Louisville, Thomas Opie, of Baltimore, and T. Gaillard Thomas, were added to, and Dr. Thomas Addis Emmet, of New York, was stricken from, the list of Vice-presidents.

In the Section of Ophthalmology, Dr. E. Williams, of Cincinnati, was substituted for Dr. Henry D. Noyes, of New York, as President, and Dr. Noyes and Dr. E. L. Holmes, of Chicago, were made Vice-presidents.

In the Section on Otology, Dr. C. H. Burnett, of Philadelphia, was stricken from the list of Vice-presidents and placed on the Council, and Drs. A. M. Wilder, of San Francisco, and D. S. Reynolds, of Louisville, were made Vice-presidents.

In the Section of Dermatology and Syphilis, Dr. J. M. Keller, of Hot Springs, Ark., was made Vice-president.

In the Section of Laryngology, Dr. Lefferts was displaced as President, and Dr. J. N. Mackenzie, of Baltimore, substituted, and Dr. M. F. Coomes, of Kentucky, was made a Vice-president.

In the Section of Public and International Hygiene, Dr. Ezra M. Hunt, of Trenton, New Jersey, was stricken from, and Drs. J. L. Cabell, of Vir-

ginia, A. L. Carroll, of New York, and J. N. McCormick, of Bowling Green, Ky., were added to, the list of Vice-presidents.

In the Section of Military and Naval Surgery and Medicine, Drs. Donald MacLean, of Ann Arbor, P. A. Hooper, of Arkansas, and E. H. Gregory, of St. Louis, were made Vice-presidents.

In the Section of Practical and Experimental Therapeutics, Dr. E. R. Squibb, of Brooklyn, was added as a Vice-president.

In the Section of Diseases of Children, Dr. Abraham Jacobi, of New York, was stricken out as President, and Dr. J. Lewis Smith, of New York, substituted, and Dr. DeLaskie Miller, of Chicago, was added as a Vice-president. — *Medical News*.

## THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION IN BOSTON.

The following resolutions were adopted at a meeting of the physicians of Boston concerned in the organization of the Ninth International Medical Congress, and held in that city July 2d:—

*Whereas*, we had been led to believe that the authority to organize and control the Ninth International Medical Congress had been permanently delegated by the American Medical Association to its original committee, thus providing against any radical changes in its published programme, and

*Whereas*, the American Medical Association has revised the action and annulled appointments of that committee in a way which we regard as detrimental to the interests of the medical profession of America and fatal to the success of the Congress;

*Therefore*, be it resolved that we, the undersigned, members of the medical profession in Boston and vicinity, concerned in the organization of the Ninth International Medical Congress, decline to hold any office in said Congress as now organized.

Robert Amory.	Francis Minot.
H. P. Bowditch.	J. R. Chadwick.
G. M. Garland.	F. I. Knight.
R. T. Edes.	C. F. Folsom.
O. W. Holmes.	Hasket Derby.
J. J. Putnam.	S. J. Mixer.
G. H. Lyman.	R. H. Fitz.
Jacob L. Williams.	C. J. Blake.
S. G. Webber.	Thomas Dwight.
H. W. Williams.	J. C. Warren.
T. M. Rutch.	O. F. Wadsworth.
H. P. Walcott.	E. Wigglesworth.
Thomas Fillebrown.	

## THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION OF PHILADELPHIA.

A MEETING of the members of the medical profession of Philadelphia concerned in the organization of the International Medical Congress of 1887, was held at the Hall of the College of Physicians, on Monday, June 29th, Dr. Alfred Stillé in the chair. Dr. David W. Vandell, of Louisville, was present by invitation.

After hearing a report of the proceedings of the new committee, at its meeting held in Chicago last

week, and after considering the changes in the organization which were made, including the restriction of the scope of the membership by which a large proportion of the profession of the country would be excluded from the Congress, the following preamble and resolution were unanimously adopted:—

*Whereas*, Certain serious changes have been recently effected in the preliminary organization and rules for the International Medical Congress of 1887, it has seemed desirable for the members of the General Committee and the officers of the Sections resident in Philadelphia to meet for consultation; and

*Whereas*, It has appeared that these changes are inconsistent with the original plan, and detrimental to the interests of the medical profession in America, and of the International Medical Congress; therefore, be it

*Resolved*, That we, the undersigned, consider that our duty to the profession and to ourselves requires us to decline to hold any office whatsoever in connection with the said Congress as now proposed to be organized:—

## Correspondence.

### EVEN DIVISIONS OF CLIMATE BASED UPON COMBINED ATMOSPHERIC HUMIDITIES.

DENVER, COLORADO, June 27, 1885.

*Mr. Editor*.—As your journal contained quite a full report of the proceedings of our American Climatological Association (first two numbers for June), I have permission to correct the mistakes which resulted from my allowing my paper to be presented *in my absence*. Had I been able to be present I should have endeavored to hold the discussion to the subject of my paper: "The Even Divisions of Climate Based upon the Combined Atmospheric Humidities," as illustrated upon my seasonal climatic maps of the United States. As there was an unwillingness to pass judgment upon these divisions (which, I believe, are the first of the kind ever presented to the medical profession), and, as the discussion turned upon the therapeutics of climate, I assume the subdivisions as made on my charts, under the two heads *moisture* and *dryness*, were not objected to. Especially is this a fair conclusion since the very important element of *soil moisture* must have its appropriate influence everywhere (except for limited areas) upon the humidities of the air,—relative and absolute humidity, and in a less degree cloudiness,—and so upon the various coloring of the climatic maps. These charts give the general averages for the whole country without reference to any particular frogpond or region productive of soil moisture. Therefore, as might be expected, those regions bordering on the oceans and lakes, or lying low in the interior, most naturally come out into

the dark-blue shades of extreme moisture. If the Adirondacks and portions of the Alleghany range, rightly esteemed as health resorts because of their sandy soil, free drainage, etc., are not properly represented on these charts it is because there are no signal-service stations there to indicate the shades of dryness to which those desirable localities belong.

Allow me to correct a statement in your report. You say: "Dr. Denison's view was that the principal elements of a desirable climate were dryness, elevation, and equability of temperature." That was not my idea at all, but may have been gathered from some statement made in the discussion of my paper. I would say the chief elements of desirable climates for phthisical patients are dryness, coolness, sunshine, and elevation. With these qualities I am willing to accept a due amount of variability of temperature, which is their natural result, just as equability is synonymous with warmth and moisture of atmosphere.

The statement attributed to me in your journal is inconsistent with the following quotation from my last year's report to the Climatological Association: "Hitherto it has not been customary for climatologists to see any good in variability. They have rather preferred to champion its opposite—equability. It does not seem to have occurred to them that the qualities which they praised, such as clearness and purity of atmosphere,—especially its freedom, with increasing elevation, from disease germs and the evidences of the lower forms of life which thrive on warmth, moisture, and equability,—are largely due to the great seasonal and other ranges of temperature, and to the nightly chilling or perhaps freezing of the atmosphere. It is not necessary to introduce any argument of a speculative character. Statistics prove, beyond the possibility of successful contradiction, that variability is a distinguishing attribute of really dry places,—whether elevated above sea-level or not,—and that equability is, as a rule, characteristic of a uniformly damp atmosphere." In proof of this the fifteen United States signal stations giving the greatest mean daily range of temperature average 28.7 deg. F., and are the really dry places, such as Yuma and Prescott, Arizona; Visalia, California; Forts Davis and Elliot, Texas; and West Los Animas, and Denver, Colorado; while the fifteen stations of least daily range average 11.9 deg., and are uniformly moist places, such as Eastport, Maine; Buffalo, New York; Barnegat and Sandy Hook, New Jersey; Cedar Keys and Key West, Florida; Hatteras, North Carolina; Galveston, Texas, and San Francisco, California. Still stronger evidence is obtained by averaging the daily and monthly ranges of temperature for all signal stations located in the different belts representing the divisions of climate on my seasonal climatic maps. The result is as follows:—

Stations of	Means of Daily Ranges.	Means of Monthly Ranges.
1. Extreme dryness.	36.51° F.	53.65°
2. Moderate dryness.	29.63°	49.38°
3. Moderate moisture.	17.09°	15.48°
4. Extreme moisture.	13.61°	41.55°

"The places of extreme dryness are more than twice as variable in daily temperature as those of extreme moisture, while the monthly means regularly decrease in variability at the rate of about four degrees for each division of climate from the extreme of dryness to the extreme of moisture." I believe too much attention has hitherto been given to equability and the precise variations in temperature, and too little to other qualities and conditions of the atmosphere.

I was surprised to learn that any one who is so much of an authority on climatology as Dr. Bell, the able editor of *The Sanitarian*, should bring forward the

argument based upon the nearly equal proportion of deaths from consumption in Colorado and Florida without even mentioning the importation into those States of the cases furnishing the mortality from this disease. In America, as in Europe, the migration of invalids, from causative to remedial climates, is becoming such an important factor in the treatment of chronic lung diseases that no census statistics are of any value without accounting for this effect. As to the origination of the disease in Colorado, I canvassed the physicians of the State several years ago, with decidedly confirmatory results in favor of an "approximate immunity from consumption" at six thousand feet above sea-level (*Rocky Mountain Health Resorts*, p. 100). In my practice of twelve years in Colorado it has been very seldom that I have known of the origination of phthisis here, and with the carefully kept records of nearly twelve hundred cases of asthma, phthisis, chronic pneumonia, etc., I do not remember to have written a certificate of death for one uncomplicated case of phthisis originating in Colorado. Of course there are such cases; I have one under my care at the present time. As civilization progresses here, it will not be strange if the disease is much more frequently met with in thickly settled districts, made up as they are of a considerable scattering of regenerated invalids.

In Denver, physicians (in making out certificates of death) are requested to state where the disease was contracted. I learn from our Health Commissioner that for the year ending with May just passed there were 151 deaths reported from chronic pneumonia,

phthisis, and consumption, and only eleven, including the chronic pneumonia cases, were reported as originating in Colorado, the information desired not being given in about half the cases.

In making comparisons between Florida and Colorado it should be noted, also, that invalids go to Florida just for the winter, while they come here, from the South as well as North, if possible, to live; that is, to fight it out to the end. Finally, the weight of evidence is so decidedly in favor of elevation as an important factor in the climate for the consumptive, that it will not answer for any one, who has not personally investigated the Rocky Mountain regions, or similar elevated resorts, to say that nothing has been proved for elevation. Everything has been proved, since all the most desirable attributes — dryness, coolness, sun-line, stimulation of increased atmospheric electricity, sandy soil and perfect drainage, and last, but not least, *purity of atmosphere* — are favored and increased with elevation above sea-level. Besides, and above all this, there are physical effects of the lessened atmospheric pressure, chiefly made known upon respiration and the pulmonary circulation of blood, which are remarkable for displacing diseased by healthy action — effects which are testified to by many who have personally investigated the subject at various elevations, and by such distinguished climatologists as Dr. Hermann Weber and Prof. C. T. Williams, of London, Prof. H. C. Lombard, of Geneva, Professor Jourdanet, of Paris, and lately by Professor Jacoud.

Yours respectfully,

CHARLES DENISON.

Deaths reported 2,640; under five years of age 1,235; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 678, diarrheal diseases 380, consumption 336, lung diseases 175, diphtheria and croup 165, scarlet fever 50, measles 43, malarial fevers 20, typhoid fever 22, whooping-cough 19, cerebro-spinal meningitis 17, erysipelas six, purpural fever five, smallpox one. From measles, New York 20, Philadelphia and New Haven seven each, Boston three, New Orleans and District of Columbia two each, Buffalo and Nashville one each. From malarial fevers, New Orleans 11, New York nine, Brooklyn five, Chicago three, Baltimore and District of Columbia one each. From typhoid fever, Chicago six, New York four, Philadelphia three, Boston and Charleston two each, Baltimore, Providence, New Haven, Lowell, and Salem one each. From whooping-cough, New York 10, Philadelphia five, Chicago, Baltimore, New Orleans, and Nashville one each. From cerebro-spinal meningitis, Chicago and Baltimore three each, Fall River two, New York, Philadelphia, New Orleans, District of Columbia, Nashville, Lowell, Worcester, Holyoke, and Taunton one each. From erysipelas, New York four, Philadelphia, Brooklyn, Boston, and Lowell one each. From purpural fever, New York three, Brooklyn and Boston one each. From smallpox, Philadelphia one.

The meteorological record for the week ending June 27th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 27, 1885, TO JULY 3, 1885.

BROWN, H. E., major and surgeon. Assigned to duty as post surgeon, Fort Reno, Ind. Ter. S. O. 91, Department of the Missouri, June 24, 1885.

AINSWORTH, F. C., captain and assistant surgeon. Relieved from duty at headquarters, Department of the Missouri, S. O. 93, Department of the Missouri, June 26, 1885.

TAYLOR, B. D., captain and assistant surgeon. Assigned to duty at Little Rock Barracks, Ark. S. O. 139, Department of the East, July 1, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY, DURING THE WEEK ENDING JULY 1, 1885.

SHAFER, JOHN PHIL, assistant surgeon. For duty on board the United States Receiving Ship St. Louis, League Island, Penn. July 19, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING JUNE 27, 1885.

LONG, W. H., surgeon. Granted leave of absence for three days. June 18, 1885.

LESTERNES, C. S. D., surgeon. Leave of absence extended seven days on account of sickness. June 21, 1885.

WHITE, J. H., assistant surgeon. Granted leave of absence for twenty-one days. June 23, 1885.

Cases reported in Boston: measles 42, scarlet fever 35, diphtheria 31, and typhoid fever one.

In 109 cities and towns of Massachusetts, with an estimated population of 1,287,488 (estimated population of the State 1,355,104), the total death-rate for the week was 15.00, against 16.56 and 14.50 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending June 20th the death-rate was 18.3. Deaths reported 3,129; infants under one year of age 756; acute diseases of the respiratory organs (London) 196, measles 187, whooping-cough 104, diarrhoea 55, fever 34, scarlet fever 25, diphtheria 25, smallpox 104; the total death-rate for the week was 18.3. The death-rates ranged from 31.7 in Cardiff to 10.5 in Derby; Birmingham 19.8; Blackburn 25.5; Bradford 16.1; Hull 17.4; Leeds 17.7; Leicester 15.7; Liverpool 23.2; London 16.4; Manchester 25.5; Nottingham 21.7; Sheffield 20.8; Sunderland 17.5. In Edinburgh 18.9; Glasgow 22.9; Dublin 27.5.

For the week ending June 20th in the Swiss towns there were 35 deaths from consumption, diarrheal diseases 26, lung diseases 10, typhoid fever five, diphtheria and croup three, purpural fever three, whooping-cough and erysipelas two each, smallpox one. The death-rates were: at Geneva 21.3; Zürich 13.6; Basle 13.6; Berne 20.7.

METALLIC POISONING FROM CANNED FOODS.  
WITH A REPORT OF SIX CASES OF POISON-  
ING FROM CANNED TOMATOES.<sup>1</sup>

BY FREDERICK F. DOGGETT, A.B., M.D.

CONSIDERING the vast amount of canned food consumed and the chances of metallic poisoning in its use, it is certainly remarkable that so few cases of such poisoning are on record; hence the interest of the cases reported in this paper. From a hasty search of the literature of the subject, drawing references from the five volumes of the *Index Medicus*, as well as other sources, but comparatively few cases have been found. Most of these have occurred in England and America; but few in France and Germany, this being probably due to the fact that much less canned food is used in the two latter-mentioned countries.

In addition to the above, I have collected together certain hints about the process of canning foods and the appearances of bad cans and their contents, whereby, in cases of lead-poisoning or irritant poisoning, if we suspect canned food as the cause, we may arrive at some opinion as to the suspected can and its contents; and this will be found to be a most practical help to us as practitioners.

## CASES OF POISONING FROM CANNED TOMATOES.

CASE I. On the fifteenth of May, 1883, I was called to see Mary H., aged eighteen, who gave the following history: Previous to May 1st had been healthy. About that time she began to complain of nausea, with occasional vomiting, frequently metallic taste in mouth, anorexia, unusual constipation, interrupted by occasional diarrhoea, accompanied by much pain and tenderness over stomach and abdomen; also pains in the limbs and increasing weakness, so that she was obliged to give up work. She also complained of short breath and frequent palpitation of heart.

Physical examination, May 15th. Complexion anæmic, with slight jaundice; tongue coated; breath fetid; gums spongy, and a marked blue line at junction with teeth; abdomen slightly tympanic and tender on pressure, which tenderness was increased on deep pressure; respiration shallow; 23 to the minute; pulse irregular and about 110 beats to minute. To test muscular weakness I ordered her to get out of bed into a chair, from which she had to be assisted to bed again. The extensors appeared no weaker than the flexors. Urine rather scanty. A specimen which was examined showed it to be concentrated; no albumen present; slight sediment and no casts.

CASE II. Ann H., aged sixteen, sister of the above, was complaining about the twenty-fifth of previous month. About May 1st was so sick as to take to her bed, where she had been for two weeks, but had much improved by the twelfth of May. She also had a metallic taste in the mouth, constant nausea, with a "sinking" feeling, as she described it, with occasional vomiting; great constipation; tender and painful abdomen; anorexia; much loss

of flesh; great muscular weakness; some dyspnoea and palpitation. Physical examination showed a blue line on the gums, which were, as in the other case, tender and spongy. The pulse was 150 a minute; temperature, which was normal in case I., was 101.5 F.; respiration 25, and shallow; skin sallow; countenance dull; breath fetid; abdomen flat and hard.

In this case the symptoms were said to be mending. She had eaten scarcely anything in the previous ten days. She had been feverish at different times during the illness, though generally cool; urine scanty and difficult of passage.

CASE III. Kate H., another sister, twelve years of age, was so ill from May 2d to May 12th that she could not go to school. The symptoms from which she suffered, as described to me on May 15th, were substantially the same as those in cases I. and II., in addition to considerable headache and loss of sleep. On May 15th the pulse was weak and irregular, and 125 beats to the minute; and, though attending school, she looked anæmic, and complained of being always tired and with no appetite; there was no blue line on the gums. She had previously been very healthy. Her sickness began with diarrhoea.

CASE IV. James H., brother of above, eight years old, was well up to the first of May, and then was sick in bed for one week. The most prominent symptom in this case was constant nausea, with frequent vomiting; diarrhoea present at first, followed by constipation. Many of the symptoms of the above-described cases were present. He went to school by May 12th, but still suffered from nausea and occasional vomiting. This case was not examined for the blue line on the gums.

CASE V. Elizabeth H., age fourteen, of the same family, between May 10th and 13th had two days of diarrhoea, nausea, and vomiting, and puckering taste in the mouth. On May 15th was at school and feeling in usual health.

CASE VI. Nellie H., age three, was sick for a few days, following the tenth of May, with diarrhoea, vomiting, and great complaint of abdominal pain. She also was said to have had some fever. Pretty well on May 15th. There was no blue line on the gums in cases V. and VI.

CASE VII. Mary H., age forty, mother of the above-mentioned children, said that she had lost flesh for a month past from April 15th to May 15th, had had a metallic taste in her mouth from time to time, with sinking at stomach, nausea, diarrhoea alternating with constipation, muscular weakness, dyspnoea, palpitation, anorexia, and abdominal tenderness.

Physical examination showed the pulse to be 130 a minute; respiration frequent and shallow; skin sallow; a blue line on the gums, with fetid breath and coated tongue.

The presence of the characteristic blue line on the gums in three of the above seven cases; the presence of colic, great muscular weakness, constipation, and nausea, with the frequent metallic taste in the mouth in four of the cases—all point to lead-poisoning as the cause of the above symptoms, accompanied most probably by a still more irritating metallic poison.

<sup>1</sup>Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, April 8, 1885.

On inquiry the mother told me that about the middle of the previous month—times being hard with the family—they bought a large supply of canned tomatoes very cheap. One or two cans a day were consumed in a family of eleven persons for many successive days; on some days three or four cans were used. Some of the cans left a metallic taste in the mouth, or “puckering,” as she described it. In two or three instances this was so objectionable that the can was thrown away. Some of the cans were rusty on the inside of the cover or bottom. One can she remembered in particular, about May 9th or 10th, half of which had to be thrown away, though the children ate some of it in the form of soup. Most of the cans were palatable and apparently good.

The utensils used by the family in cooking were examined for presence of lead, with negative results, there being no “enameled” ware in use.

As two other families who were healthy used water through the same pipes, the water could not be blamed.

A can partly filled with tomatoes, from the first lot used by the family, was taken for examination. This was said to be a “good can”; and so it proved to be, so far as the presence of lead was concerned, for from the concentrated filtrate from the above, first evaporated to dryness and burned and treated with nitric acid, no signs of lead were got by the sulphuric acid, potassic iodide, or bichromate of potash tests.

This can was labeled “K . . . Imperial Brand,” and, having found where the family obtained their cheap supply, I went to the same place and got two cans of the like brand. The cans were some three cents cheaper than the usual price, much shoddy, and without date of time of preparation. There was no evidence of rosin used in soldering, either at the joints of the head, bottom, or side. On opening, one can was found to be oxidized in patches about the joint at one end and the liquid had a slightly metallic taste, as two other persons besides admitted. The juice of the two cans was treated by evaporating to dryness, burning, and filtering with nitric acid, and testing the filtrate. No lead was found in one, but in the can with the metallic-tasting contents lead was found. As to the innocuousness of the other can, the part remaining was used without any bad effects.

As further evidence bearing on the inference that the poisoning was due to eating the tomatoes we have the negative proof that the four other members of the family, who ate not at all, or very little, of the tomatoes, remained well. The detection of lead in a can of the brand eaten is only presumptive evidence that some of the cans used contained lead. On the other hand, the medical and circumstantial evidence alone is enough to stamp them as cases of metallic poisoning from the canned tomatoes. In cases I., II., and VII. the symptoms of lead-poisoning were most prominent, the symptoms of an irritant poison being subordinate. Cases V. and VI. were cases of irritant poisoning, without any symptoms of lead. Cases III. and IV. were mixed cases of lead and irritant poisoning. They all recovered; cases I., II., and VII. taking the longest time.

That tin or zinc might also have been present in

some of the cans, as well as lead, is possible and is made probable from cases IV., V., and VI.; for in these cases the sickness would point to the presence of a more irritating poison than lead, and acute poisoning from lead is very rare.

Dr. Johnson, in a paper read before the New York Legal Society, April 8, 1884, gives an account of several cases of corrosive poisoning from zinc and tin chloride in canned goods. The zinc chloride is with tin chloride formed into a flux or solution, and is used in soldering the ends and sides of the cans instead of rosin and ordinary solder, than which it is much more convenient though very poisonous, and in spite of great caution it may at times get into the contents of the can.

So certainly is this means of poisoning from canned food recognized that the State of Maryland has passed a law forbidding the use of the poisonous zinc and tin chloride amalgam in canning food. As above noted, there was no mark of rosin to be seen about either the ends or sides of the cans examined. Cases V. and VI. were taken violently sick after eating of the bad can used about the ninth or tenth of May. Such acute symptoms from lead alone would be very rare, even if there was considerable present. Both these cases recovered promptly, which would not have been the case had they ingested at that time a large dose of lead. In all the cases diarrhea was very marked at first, which is not usually the case in simple lead-poisoning. In the cases where the pulse was especially examined there was great disturbance, it being irregular and very quick, from 120 to 150. In simple lead-poisoning the pulse is slow, according to Flint. According to Reeve, it is sometimes quickened. But in poisoning from irritant metallic poisons, as copper, zinc, or tin, the pulse is small, irregular, and quick. Stannous chloride is very poisonous; the symptoms from poisoning by this salt resemble corrosive-sublimate poisoning, though much milder.

It is improbable that in these or similar cases of poisoning a poisonous tin salt could come from the wall of the can itself; though there is some reason to suppose that lead may so contaminate the contents of the can. First in regard to tin:—

In 1878, A. E. Menke reports that in an analysis of many specimens of canned lobsters, apples, and pineapples he found tin present in the contents of all, and in the latter as much as 1.3 gr. to lb. This was reported in the *Chemical News* (England).

In 1880, Mehner, in the *Analyst* (Engl.), reports that he found tin present in canned asparagus, tomatoes, peaches, pineapples, cherries, corned beef (five brands), oysters, sardines, salmon, mutton, chicken, turkey, and canned milk (three brands). In the milk there was  $\frac{1}{10}$  gr. to lb. In soup  $\frac{1}{2}$  gr., and in oysters  $\frac{1}{10}$  gr.

Later, Wynter Blyth, in a report to the Vestry of Marylebone, found, in twenty-three samples of tomatoes, in cranberries, apricots, and pineapples, larger quantities in form of stannous hydrate, which is much less active than stannous chloride. In some of the above specimens he found as much as 14.3 gr. per lb., and the average amount in all examined was 5.2 gr. to lb. In some, even the juice had a metallic taste. In some cans the tin was corroded. By experiments on Guinea-pigs with stannous hydrate,

Orfila found that it took .171 gm. per kilo in weight of body of the animal to produce death. Assuming man equally susceptible to the poison as the Guinea-pig, it would take from three to four drachms to kill a man. It is probable, however, that small repeated doses act more powerfully, as with mercury. Such a result is likely to follow after long-continued living on an exclusive canned diet, as on long voyages. Such a state of affairs was found to be present among the officers and crew of the ill-fated *Jeannette*, on their memorable retreat over the ice to the coast of Siberia. The goods had been canned for two winters and two summers, and had been a constant article of diet. The longer the vegetable and fatty acids are in contact with the metal the more will be the likelihood of a poisonous stannous compound forming.

In Germany, Drs. Unger and Bödlander examined a great number of cans of fruit and vegetables, and always found tin present in the solid parts as an insoluble stannous compound, the per cent. of tin being .04.

On May 5, 1881, Professor Attfield, of England, read a paper before the Pharmaceutical Society of London, detailing a large number of analyses of sixteen varieties of foods, in only a few cans of which could tin be found, even in small quantities. In his opinion a harmful quantity would produce such a disagreeable taste as to render it unfit for food; further, that the "public has not the faintest cause of alarm respecting poisoning from either tin or lead in canned food"; further, that when symptoms have been reported they have resulted from stannous or plumbic chloride, formed with hydrochloric acid in soldering, this tin salt being very poisonous. He further thinks that a poisonous tin or lead salt may be formed by contact of the fatty or vegetable acids on the metal of the can or solder when kept open in the air waiting to be used.

A commissary officer high in the United States Army has made the statement that during a series of years in different parts of the country hundreds of thousands of cans of food have been used by the army, and no case of poisoning from such food has ever been reported. That extraordinary care is used in selecting the cans in the United States service I know to be true, as a gentleman lately in the navy informs me that all swelled cans are rejected.

It is probable that a large part of the canned food at any time on hand has not been freshly canned. Hence the great resistance made to the passage of the proposed bill through the New York Legislature in the spring of 1884 by the producers of canned goods. The bill was to the effect that each can should be stamped with the date of its preparation. I have found that in "the trade" the inferior goods are known as "Seconds" and "Re-processed," which means that the cans which have failed in the first preparation to become hermetically sealed, or those which have rusted or got punctured and the inside of the can oxidized and chemically acted on by the acids of the contents, and perhaps the contents partially decomposed; such cans are superheated in steam or boiling water, resoldered, and returned to the market.

In the *British Medical Journal*, November 1,

1879, p. 707, is mentioned the occurrence of several fatal cases of poisoning from tin and zinc chlorides in the solder used in preparing canned meat. Hydrochloric acid was used in the amalgam. This occurred in Germany.

So far as poisoning from tin is concerned by formation of a poisonous compound from chemical union of acids of the contents of the can with the metal, either in the solder or from the walls of the can, or from careless use of stannous chloride in soldering, the great bulk of testimony shows that such poisoning may occur. The apparent discrepancy between Professor Attfield's testimony (although he admits poisoning may occur from tin) and other authorities is explained when we recall that they were examining different specimens.

From the symptoms and a consideration of the evidence, I think it most probable that cases V. and VI. were cases of corrosive poisoning from a salt of tin, probably of stannous chloride. Case IV. seemed to suffer more from this than from symptoms of lead-poisoning.

Having shown that cases I., II., III., and VII. were cases of lead-poisoning from eating the canned tomatoes, and having demonstrated the presence of lead in a specimen of the same brand obtained from the same source, it remains to inquire how lead may get into the contents of the can. When genuine solder is used some small quantity of lead in it may get in and be acted on by the contents, forming a soluble salt, and so be absorbed; but in all the analyses to which I have had access this has never been considered of consequence enough to suggest poisoning, except with a strong acid contents.

The other possible source of the lead is important. It appears that an amalgam of tin and lead is cheaper than the former metal alone, hence there is always an inferior quality of tin in the market which contains from one to ten per cent. of lead, and such tin has been used in canning foods, and lead-poisoning from such a cause has resulted. For instance, Dr. Magruder<sup>1</sup> publishes a case of severe lead-poisoning from eating canned corn. He found that tartaric acid was used in preparing the corn, and that the tin of the can had a certain amount of lead as an amalgam with it. This he proved by testing the tin of the can, and he found the same to be true in several cans of the like brand which he tested. This was verified by Dr. Onderdonk, of St. James College, Maryland, who out of many cans tested found only two free from lead.

Dr. Dorsh<sup>2</sup> reports that out of a large number of cans tested he found lead as an alloy with tin in almost every case. An alloy of lead and tin is more easily oxidized and dissolved than tin alone. I have tested twenty cans of many brands, from the cheapest to the highest price, and have always found lead present in the tinning of the cans. This, too, with weak solutions of nitric acid, allowing the acid to act some time and then getting the characteristic yellow iodide of lead by dropping on a crystal of potassic iodide.

The principal examiner of chemicals in the Patent Office at Washington says that all commercial tin is alloyed with lead; and that the formation

<sup>1</sup> Philadelphia Medical News, September 8, 1883.

<sup>2</sup> Chicago Medical Journal and Examiner, September, 1878.

of salts of lead and tin when in an alloy is especially liable to take place in presence of fruit acids. Professor Wormley, of the University of Pennsylvania, gives his testimony that several cases of lead-poisoning have occurred after eating canned fruit.

In the *Philadelphia Medical Times* for May, 1883, a case of poisoning from this cause is reported. In the *Quarterly Compend of Medical Science*, July, 1883, there is reported the case of poisoning where 150 soldiers, quartered in the Tyrols, used as a cooking-utensil a dish lined with tin which was alloyed with lead; they all suffered from lead-poisoning; forty-five of them were in the hospital, and one died from this cause.

Nannin, in Ziemssen's *Cyclopaedia*, says a mild lead-poisoning may occur from the action of fatty and vegetable acids on the lead in an alloy of tin and lead. Some specimens, such as Bohemian tin, may contain ten per cent. of lead.

On the other hand, F. P. Hall,<sup>3</sup> after analyzing a number of specimens of tin used in canning food, says the tin is generally pure, and in his opinion such acids as would be present in canned food would not affect impure tin enough to cause poisoning.

The French Commissioner of Hygiene admits cases of lead-poisoning from canned food in cans made of tin and lead alloy, and suggests that a law should be made in France compelling the use of pure tin.

M. Gautier, in France, reports that no death has been traced to canned goods, but many cases of lead-poisoning have been reported from continued use of such goods.

To show how the specimens of tin used in canning goods may differ, so good an observer as Professor Remsen,<sup>4</sup> examined some of the same brand of canned corn which produced lead-poisoning in Dr. Magruder's case, and reports that lead was absent in the corn; also in the metal of the can. So that, as pointed out in reference to poisoning from a salt of tin, contradictory evidence of this kind should have no great weight, as some specimens of the same brand are good and some bad.

In the above cases of lead-poisoning related by the writer, it seems most probable that the lead salt absorbed was produced in the cans by the chemical action of a vegetable acid from the tomatoes acting on the lead contained in the alloy of the can, and possibly on a little solder which may have got in through carelessness. The writer regrets that he did not test the suspected can for lead in form of an alloy.

In general, the possible sources of danger to the consumer of canned foods are to be found in the structure of the can, the solder, or in the contents *per se*. As to poisoning from decomposed animal canned food, many cases have been reported. For instance, in the *British Medical Journal* of November 1, 1879, there is reported the account of the poisoning of twenty-one persons from eating "Chicago corned beef." The symptoms were those of an irritant poison, even proceeding to collapse, though all the cases recovered. Usually the unpalatableness of the contents is enough to warn

the consumer not to partake. The bad condition of the contents can often be foretold before opening the can; as, if air has been admitted at the time of soldering, or from improper methods of preparation, or original unsound contents, decomposition will take place and fermentative gases be formed within the can, together with the acids; this will cause the ends of the can to bulge outward. In "the trade" such cans are called "swells." Such cans should be rejected. A recent writer on the subject has said that a bad can will have rattling contents on being shaken. I think this proves nothing as to the badness of a can; for, in case of between thirty and forty cans of tomatoes, the contents were found perfectly good on eating; though before opening, the contents of the cans rattled on shaking.

Among the cheaper grades of canned tomatoes I have occasionally found that the contents will curdle milk, though it may taste and look as usual. I think in such cases that some fermentation has taken place, and in the process a vegetable acid has been found to curdle the casein of the milk. Ordinarily the juice of the tomatoes mixes with the milk without curdling it. Accordingly, if a little of the juice of a suspected can of tomatoes will curdle an equal quantity of sweet milk, one would be justified in assuming the presence of some vegetable acid in the tomatoes. It is only a question of amount of acid and length of time it remains in contact with the surface of the can that will determine the presence of a lead salt in the contents of the can. The contents may have a metallic or astringent taste, as in the above-reported cases, and then it should be rejected.

As to the solder, there is danger of corrosive poisoning from presence of tin, or zinc, or lead, or all. For it is now, or has been, a custom, within a short time, to use a flux of tin and zinc chlorides, and with hydrochloric acid to solder on the head of the can. This is so poisonous that a small quantity in the can would do much damage. The ordinary way of soldering is with a solder of tin and lead with rosin, which last in melting leaves its trace around the head and at the side of the can. Hence, reject a can not showing this, as then the presumption is that the poisonous solder has been used. A small piece of the tin and lead solder may fall into the can, but as yet has never been shown to have done harm.

However, if a large surface of solder is left on the inside of the can by the solderer, and if acids were formed in the can, there would be a good chance for lead salts to be formed; for ordinary plumber's solder contains seventy-five per cent. of lead—a much larger amount than would be found in the turning of the can.

The acids likely to be formed by fermentation or decomposition of the contents of the can are, from vegetables and fruits, acetic acid, malic, citric, and tartaric; from meats or fish mostly butyric acid.

As solder is somewhat expensive in quantities, and an unskilful solderer will use more than a skilful one, solder in sticks is served to each man. We may see from this that some cans would have more solder on the inside than others. Further than this, to solder quickly and with an economy of

<sup>3</sup> *American Chemical Journal*, vol. ix.  
<sup>4</sup> *Philadelphia Medical News*, January 19, 1884.

solder, with rosin as a flux, requires a skilful workman; whereas the beginner uses much solder, and at first perhaps hydrochloric acid instead of rosin as a flux. The acid in contact with the solder forms the very poisonous stannous chloride, which, in the hands of the beginner, is all the more likely to be used carelessly and get into the contents of the can.

The manager of a canning-factory makes such a distinction between a good and bad solderer that each man is often made to put his mark on each can made, so that it may afterward be identified.

As to the can itself, if pure tin alone were used, the formation of a poisonous stannous compound sufficient to produce marked symptoms, even if eaten for a long time, would not be possible, as has been absolutely demonstrated. Some innocuous stannous hydrate would always be present, however.

On the other hand, if lead in any quantity is used as an alloy with the tin, then is lead-poisoning likely to follow, provided enough is eaten and over a considerable time. Especially is this likely to occur in goods kept for a long time, or when the contents are left in such a defective can exposed to the air, or when such cans and their old contents have been "reprocessed." These last can be detected, as there are then to be seen two soldered-up holes instead of one in the head of the can; the sound cans have but one soldered-up hole. The contents should never be allowed to stand long in the can after opening, especially in warm weather. The can should contain on the label the name of the manufacturer and place of putting up, and be labeled "Standard." If a can has rust about the cap, air has very likely got in and the contents have decomposed and formed possible poisonous compounds with the wall of can or solder; hence, reject such cans.

These points, in connection with the symptoms in any suspected case of poisoning from canned foods, will enable the practitioner to make a diagnosis. From consideration of the above facts he will be able to give his patients a just estimate of the dangers of poisoning from canned food, showing that such danger is small if the above precautions are attended to. Considering the vicissitudes that canned foods must pass through under the hands of the canmakers, the solderers, and the tradesmen, with the chance of being "reprocessed," or kept for years before reaching the consumer, it is surprising that so few cases of poisoning therefrom have been reported.

## TWO CASES OF RETRO-PHARYNGEAL ABSCESS.<sup>1</sup>

BY THOMAS ANDREY DE BLOIS, M.D.

ABSCESSES beneath the posterior wall of the pharynx should be interesting to every one, at least on account of the rarity of their occurrence, for whereas few have seen more than one or two cases, yet almost everybody has seen one. They should be quite as interesting to the general practitioner as to the specialist, for they are more likely to occur in

the practice of the former than the latter, on account of their usually being found in children, and of their being opened as soon as found. As to what constitutes a retro-pharyngeal abscess: We should carefully exclude the peritonsillar, or that which is found in the loose tissue around the tonsil, and in so doing might select the posterior pillar of the fauces as the anterior boundary; then any abscess posterior to these pillars, and situated beneath the pharyngeal wall, and from the vault of the pharynx above to the larynx below, should be included under this head.

It has been my good fortune to see five of these cases, two of which occurred last month and within one week of each other, both being in very young subjects.

On the second of March, Dr. G. W. Galvin, being obliged to leave the city, requested me to see the child of Mrs. S., in South Street. I found the little boy, only three months old, lying on a lounge on his side. He was markedly anæmic, and breathed with great difficulty. The mother reported that the child had eaten nothing for twenty-four hours, and that during the preceding night they thought he would die in one of the paroxysms of dyspnoea, of which he had had several. What struck me particularly in the child was that the head was not thrown back, as I had expected to find it.

In the history of the case, as given by Dr. Galvin, he had found an enlargement which seemed to point internally; this disappeared, and two swellings were found on the same side of the neck externally. One of these he incised, but found little, if any, pus; subsequently the tumor was found in the throat.

Placing the child in its grandmother's arms, with its back to the light, by the aid of the head mirror, and a very small teaspoon (for the arch of the jaw was too small to admit the smallest-sized tongue-depressor), I gained an excellent view of a red swelling a little to the left of the middle of the pharynx, a large part being obscured by the tongue; there was also undoubtedly fluctuation on touch with the finger. Having with difficulty obtained permission to open the abscess, and after instructing the woman who held the child to reverse him, when told, as she would an hourglass, I got the point of a bistoury, well guarded with cotton, into it, and cut down till I reached my spoon. The child was inverted promptly, and the pus gushed out on the floor in large quantities, leaving no room for doubt that if the abscess had burst during sleep suffocation would have ensued. Having no syringe with me which would work, I had to wipe out the mouth repeatedly with a wet napkin.

The patient now seemed to be much weaker than before the evacuation of the pus; he was laid on the side with his head lower than his body, and occasionally a few drops of brandy and water were given, and finally the child took the breast. The following morning he was reported as being convalescent.

My second case, which I saw March 8th, was a patient of Dr. Disbrow's, a female child of seven months, living in Columbia Street, daughter of Mrs. H. The mother had been a patient of mine at the

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, April 8, 1885.

Dispensary about two years ago, and while pregnant had developed a peculiar and I suppose hysterical affection of the larynx, taking the form of aphonia, due to want of tension of both vocal cords; this persisted in spite of all remedies until after parturition, when it disappeared spontaneously.

Mrs. H.'s child was exceedingly pale and sick, but had been able to eat, and resisted with violent struggles all attempts to see the fluctuating swelling, which could be felt in the posterior wall of the pharynx, and which pushed forward the velum until the uvula stuck out almost erect. Only once before I cut was I able to sight the abscess, which, unlike the first one, was almost white, and stood in the median line, but this child's head was not thrown back any more than the other. I followed as far as possible my former procedures, except that in addition I had the father to hold the child's head. I think I must have been fifteen minutes trying to bring the abscess again into view, and when I did I cut exactly as I had before, except that the incision was not so long. The child was also turned head downward, and the mouth was syringed, the pus pouring through both nostrils, but there was no blood. On digital examination there appeared to be a second tumor below the first, which afterward seemed to drain off through the same opening, but it must have filled up again, for I heard of its opening spontaneously the next day. After the operation it appeared as if the child were about to go into collapse, the pulse could not be felt, the eyes closed, and she ceased to breathe; wine was given, also the breast after she had rallied a little, but she could not nurse. Yet I felt sure that none of the discharge had entered the lungs, and on auscultation with the stethoscope they seemed to be quite clear of fluid. I tried all I could to rally the child, but when I left the house it seemed about an even chance whether she would live or die.

The next day, however, I received a letter from the father, stating that the baby was "playing on the floor as lively as a kitten."

Last year I mentioned a third case of pharyngeal abscess, which occurred at the Boston Dispensary, in a man, D. M., aged twenty-seven years, and whom I saw on the twenty-second of November, 1880. He had what appeared to be an acute pharyngitis, but he returned on the 24th with his head a good deal bent backward, and a large swelling behind the pharyngeal wall, which fluctuated. I never had seen a pharyngeal abscess before, and when I passed a bistoury into it was very much surprised at the large amount of pus which flooded the patient's mouth and throat. I quickly seized him by the hair and forced his head down into a spittoon which was on the floor, and he was thus enabled to clear his throat and nasal cavities without any of it entering his larynx.

Soon after this I was allowed to see a case in the service of, I think, Dr. Haven at the Dispensary. A little child, perhaps two years old. The head was carried markedly back into the opisthotonus position, and there was so much pain and so little fluctuation that I gave it as my opinion that it was a case of disease of the cerebral vertebrae, but it afterward went to the Children's Hospital, and was finally aspirated, I believe.

About a year ago I saw a fifth case in consultation with Dr. Galvin; the child was young, and the swelling was so near the posterior pillar of the fauces that I always felt some doubt as to its being a true pharyngeal abscess. Dr. Galvin cut into it while I was present, but got only blood; either that night or the next day he cut again and got pus.

According to MacKenzie and the authorities he quotes, these affections are idiopathic. Bokai at least counts one hundred and twenty-nine such out of one hundred and forty-four cases, whereas Cohen, quoting from Gautier, states that "it appears to be idiopathic in some few instances only."

In the last volume of the Transactions of the American Laryngological Association, in the exhaustive article by Dr. J. O. Roe, of Rochester, on this subject, this gentleman quotes twelve different authorities who seem to hold twelve different opinions as to the causation of these affections. They range all the way from suppurative in the region of the perinaem, by Nélaton, to chronic "smuffles," by Fraenkel.

In none of the five cases which I saw was there any assignable cause; there was no syphilis nor other constitutional affection that I could learn. None of the cases appear to have been well nourished, but no worse than is frequently found in that sphere of life. The hygienic surroundings were what appear to be inseparable from poverty in a large city.

In the first two cases which form the subject of this paper it will be observed the extreme prostration which followed the evacuation of the contents of the abscesses; in both, the children luckily recovered; but would they have survived the operation had they been less strong?

Of course, incision is the procedure which most would follow in dealing with these cases; but may not death in some instances ensue from shock? Would aspiration be any safer than rapid evacuation? and if emptied by the aspirator, is not the probability of the abscess refilling much greater?

I should also like to draw attention to the fact that the heads in these two cases were not carried in what I always believed to be the "pathognomonic" position, — so that symptom was lacking.

One child was unable to swallow, while the other appeared to have no difficulty in doing so, although its abscess was larger and appeared to obstruct the pharynx more.

As to the incision, it has variously been advised to make it longitudinally, transversely from below upward, etc., but it seems to me that the cut should be made from as near the soft palate as you can get, without injuring it, down until you come to the depressor, which will protect the tongue, and of course the more dependent portion of the abscess should be laid open if possible.

The holding of a child with its feet in the air, or the forcing of an adult's head toward the floor are precautions worth observing, for even in the case of the one grown person mentioned, the liberation of the pus was so sudden and overwhelming, that it was no easy matter to clear the throat quickly.

I have never seen a case of retro-pharyngeal abscess due to disease of the spine, but it is this class that refill, recur, or do not get well. The idiopathic and the traumatic begin and end with the one attack.

THE TREATMENT OF PULMONARY DISEASES BY MEANS OF "PNEUMATIC DIFFERENTIATION."<sup>1</sup>

BY VINCENT Y. BOWDITCH, M.D.

It is my purpose to speak of a new method of treatment for pulmonary diseases, which was brought to my notice not long since in the Journal of the American Medical Association, February 14, 1885, in which the writer referred to an article in the *New York Medical Record* of January 17, 1885, by Dr. Herbert F. Williams, of Brooklyn, New York, who speaks of the "Antiseptic Treatment of Pulmonary Diseases by means of Pneumatic Differentiation," and records with their results a series of cases which have undergone this method of treatment.

I speak of it as a new method, because I believe it to be a step forward in the treatment of one of the most formidable diseases with which we have to contend, and whatever may be the results of future investigations, I deem it worthy of the careful consideration of all members of the regular profession, and if the results are not what we have been led to hope for, we can, at least, say that no harm has been done by our endeavor to find a new weapon against a terrible disease.

The treatment of pulmonary diseases by the inhalation of compressed and rarefied air has been for several years used by well-known scientific men with apparent success in many cases in Europe, especially in Germany, and to a much greater extent than in our own country, where I think I am right in saying that comparatively little attention has been paid to either method by members of the regular profession. Various irregular practitioners have used inventions of their own, having more or less similarity to each other, for the disease in question, but whether from the fact that such people usually keep their inventions to themselves, or because they have been proved to be utterly worthless, no marked movement toward a general adoption of such therapeutic measures has been made.

It has been my good fortune in studying the subject to come across the methods of treatment of one or two irregular practitioners, which at first seemed to resemble closely that adopted by Dr. Williams, but which upon closer examination were found to differ in essential points. Of these methods I shall speak more fully later.

The treatment of pulmonary diseases by means of compressed and rarefied air, as used in Europe, is meant chiefly to accomplish the same result as removal to some different section of the country where the air has the requisite degree of density or rarefaction for the treatment of the disease in question. To obtain this, air-tight compartments are constructed, in which the patient sits for a given time, and the air is then partially exhausted or compressed, according to the needs of the case, which treatment is continued for a certain number of hours in the day for several weeks, or possibly months, and the results seem to justify the fact that

these methods are in constant use in Europe.<sup>2</sup> Various portable instruments have been devised by different scientific men for inhalation of compressed air, and *vice versa*, the best known being the apparatus of Waldenburg, of Tobel, of Schnitzler, or of Geigel and Meyer; also another of J. Solis-Cohen,<sup>3</sup> of Philadelphia, all being modifications of the same idea, illustrations of which I shall show you to-night, as seen in books upon the subject. It will be noticed that in the use of these last-mentioned instruments the surface of the body is exposed to the ordinary atmospheric pressure, whereas in the case of the pneumatic chambers the atmospheric pressure upon the body and in the lungs is increased or diminished according as the air in the cabinet is compressed or rarefied.

Still another method has been invented by Hauke, called by him the "Wärme," or tub, spoken of in Ziemssen's *Handbuch der allgemeinen Therapie*; but, as far as I can discover, the apparatus has not been universally used. In following out this method, a rubber hood, closely fitting about the head and leaving the face only exposed, comes down over the shoulders like a shirt. The patient is then made to lie down in the "Wärme," which in shape resembles a tub, having a close-fitting rubber cover which encircles the neck of the patient, and the hood is then fastened to the edge of the cover by means of an elastic band. The air is then partially exhausted from the interior of the "Wärme," which decreases the atmospheric pressure over the surface of the body, with the exception of the face. Upon inspiration the increased pressure of the outside atmosphere materially tends to expand the lungs from within, and the inspiratory act is greatly facilitated, whereas the expiratory effort is proportionately increased, and a calisthenic action of the lungs and chest-walls is thereby obtained to a greater degree than by the ordinary respiratory movements.

A similar method to this was adopted by an irregular practitioner, called "The Hadfield Body Receiver for the New Haven Vacuum Cure," used. I have been informed, in 1862, a sketch of which I have with me.

I have mentioned quite superficially the various methods used by the regular profession in so-called pneumatic therapeutics, so far as I have been able to learn of them, that you may be able to understand the general principles of their use, and before speaking of Dr. Williams's cabinet it is only necessary to mention the various methods of inhalation familiar to us all, used all over the world in the treatment of pulmonary diseases; for example, inhalations of atomized sprays of different substances, of the use of rooms filled with medicated vapors, etc., all of them seeming to have met with more or less success, but too numerous to do more than mention here as they bear upon Dr. Williams's method of treatment.

<sup>1</sup>Compartments of this nature exist in Lyons, Montpellier, Nice, Stockholm, London, and at Priesdorf, also in several places in Germany, but I am not aware that any similar chambers are constructed in this country. They are expensive, and used only by experienced persons in the regulation of the various diseases, used in connection with them, and it is probably for this reason that they are not more universally used.

<sup>2</sup>Solis-Cohen's article in *New York Medical Journal* for October 18, 1881, entitled "Compressed and Rarefied Air as a Substitute for Change of Climate."

<sup>3</sup>Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, May 13, 1885.

In March, feeling much interested in what I had read of the Pneumatic Cabinet, I went to Brooklyn and was there enabled, through the courtesy of Dr. Williams, to study the apparatus thoroughly, and to examine three or four of his cases who had derived marked benefit from the use of the so-called differentiator. The cabinet is made of iron and resembles a large iron safe in general shape, in one end of which is a large, thick glass window. It is between six and seven feet high, about three feet wide, and from three and one-half to four feet long, in short, large enough for a man or woman to stand up or sit down in comfortably. Opposite the window is a heavy iron door edged with rubber and furnished with heavy bolts, all moved easily by one handle, so that the door can be instantly opened. Beneath the window is a projection in the side of the cabinet to accommodate the patient's knees when sitting with the face near the window, the same projection serving on the outside as a shelf upon which the atomizer used with the apparatus is placed. Passing through the glass window is fixed a short gutta-percha tube about one and one-half inches in diameter, having a stop-cock on the outside, and ending in a trumpet-shaped opening for receiving the spray, the inner end being fitted with a movable rubber tube and mouthpiece for the patient's use. Near the cabinet stands a cylindrical iron vessel, from which the air is as nearly as possible exhausted, communicating with the interior of the cabinet by means of a pipe and stop-cock. A barometer, connected with the inside of the cabinet to show the amount of rarefaction of air in the interior, is fastened to the outside of the cabinet.

The patient enters the apparatus and seats himself opposite the window; the door is closed and the stop-cock of the pipe connected with the vacuum is opened. The air from the cabinet rushes to the vacuum, and when the barometer shows a depression of two tenths of an inch the stop-cock is again closed. A spray, usually of carbolic acid, iodine, iodoform, or bichloride of mercury, either singly or in combination with each other, is then put in front of the inhaling-pipe; the patient is directed to insert the end of the tube in his mouth, closing the lips over the mouthpiece, at the same time compressing the nostrils with his fingers to prevent the air rushing out through his nose; the stop-cock is turned and the outside air rushes in, carrying with it the medicated spray and causing a more forcible involuntary inspiration, giving one the sensation of having taken an unusually full, deep inspiration; the patient then, by a voluntary forced expiration, exhales through the tube again, and continues these respiratory movements several times. Upon the least feeling of fatigue the stop-cock is turned and the patient, after removing the tube from his mouth, breathes the rarefied air of the cabinet again until ready for a second trial. The time occupied in this treatment varies from ten to thirty minutes, and usually daily applications are made, the greatest number given, according to Dr. Williams's pamphlet, being one hundred and thirty-five. The amount of rarefaction used in the beginning is never more than what would cause one tenth or two tenths of an inch depression of the mercury, but during the treatment a gradual increase of rarefaction may be

used, up to an amount causing a one-inch depression of the mercury, although in many cases, doubtless, even a greater degree of rarefaction could be used with benefit and without evil results.

The only peculiar sensation which may be noticed in the beginning of the treatment is a slight crackling in the ears, as the air is being exhausted from the cabinet, but if the patient be told to swallow two or three times, this symptom will entirely disappear.

It will be seen, I think, from the foregoing description of the apparatus, that what it accomplishes is two-fold in its nature, namely: it produces a much greater expansion of the lungs than is possible by an ordinary full inspiration; and, at the same time, the medicated spray being carried with much greater force than by a natural inspiration is deposited in the deeper portions of the lungs in a much more thorough manner than by any other method that I know of, as has been proved satisfactorily by Dr. Williams in a series of experiments referred to in his pamphlet.

As to the principle of his cabinet, it will be noticed that it resembles in theory the "Wärme," or tub, of Hauke, before mentioned, in which atmospheric pressure on the surface of the body is lessened, the face only being exposed to the outside air; but the simplicity of Dr. Williams's method, by which the patient is enabled to undergo the process without the discomfort of putting on extra coverings, as in Hauke's plan, will strike every one, to say nothing of the greater thoroughness with which the purpose is accomplished. The chief merit of his cabinet lies, however, in the fact of the combination of the medicated spray with the increased strength of the inspiratory movements. For full accounts of his cases which have undergone this treatment I must refer you to his pamphlet, merely remarking that the percentage of cases which have improved is most gratifyingly large and that it must be left to the future to determine whether others meet with equally happy results. I wish to speak, however, of three patients whom Dr. Williams kindly let me examine. [Cases I., II., and IV., were read from Dr. Williams's pamphlet.]

Upon examination of case II. of Dr. Williams's pamphlet, I found him to be a young man of rather delicate build, but otherwise looking well, and to all outward appearances in good health. Percussion of the right chest showed slight dullness in that region, and upon auscultation a faint crackle was heard, and the respiratory murmur was harsh, but the gurgling sound and the amphoric quality spoken of at the first examination I did not get. The young man spoke of himself as feeling all right, but upon closely questioning him I found that he had a slight cough upon arising in the morning. Of the evident marked improvement from his previous condition as described, no one would doubt he had been enabled to resume his work a year previous.

CASE I. (a young lady), when I saw her, looked rather pale and anæmic, but her mother spoke to me especially of the condition in which her daughter was before beginning the treatment, and of her belief that she was well. Examination of right chest showed dullness and crumpling with inspira-

tion,—a marked difference from the signs noticed before,—and the patient was able to do, as far as I could learn, everything that the other members of the family were accustomed to.

CASE IV., which was complicated with empyema, looked perfectly well, showing a slight fistula in the left chest. Upon examination, all the signs of a former empyema on the left side were present. Dr. Williams also spoke of the presence of a slight rumple heard at one time under the right clavicle in the course of the disease, but after the continued use of the cabinet it disappeared, and when I examined him the respiration was absolutely pure at that point.

In regard to the first two cases it should be said that Dr. Williams does not wish to claim that they are insured against a return of the trouble: on the contrary, he believes that they both will eventually die of phthisis; but he does claim the greatest improvement and an arrest of the disease, and, as far as outward appearances are concerned, a return to health. He hopes for the greatest benefit to arise in those cases of incipient phthisis where there seems to be nothing more than a catarrhal condition of the lung, and his one desire is that his method of practice shall be given a fair trial by members of the regular profession everywhere. In those cases, moreover, of a slowly expanding lung after pleuritic effusion, the mere mechanical treatment of the cabinet can be of great assistance in promoting expansion.

In every collection of cases of this sort it is only right that we should carefully weigh every evidence for and against the justice of the conclusions drawn. In the cases enumerated in Dr. Williams's pamphlet we must think of the moral effect of the new method upon the patient. No doctor is unaware of the marvelous influence which the mind has over the body, and of the marked improvement which often takes place in the general condition of a patient upon trying a new physician or a new method of treatment. We must think, moreover, of the possibility of the enthusiasm of the inventor blinding his eyes to certain facts which must be considered, while wishing at the same time to be perfectly fair and unbiased in his statements; we must also not be too greatly influenced by the delight of friends and relatives, who, seeing a marked improvement in one dear to them, exaggerate to themselves the signs of a return to health. Nevertheless, with a collection of cases such as Dr. Williams gives us in his pamphlet, it becomes the duty of responsible physicians throughout the country to investigate the subject thoroughly in a spirit of perfect fairness and without prejudice, and to let the future decide whether others meet with equally successful results.

It has been my desire since seeing Dr. Williams's cabinet to find if any similar method of practice has been used before; and my attention was called to a cabinet used by a practitioner not of the regular profession in this city. In a pamphlet issued by him, a woodcut of his cabinet was shown which seemed to resemble almost precisely in principle that of Dr. Williams; and the description of its use as expressed in the pamphlet led me at first to believe that they were identical, with the exception that no attempt was made to use a spray in commu-

tion with the cabinet. I visited the gentleman and was received with courtesy, and the principles of the cabinet were explained to me. The description of the apparatus in the pamphlet speaks of the air being partly exhausted about the patient at his will. Upon questioning the gentlemen more closely, however, I found that the breathing-tube and stop-cock on the inside of the cabinet were not used at all in the same manner as in Dr. Williams's apparatus; and I cannot do better than quote the gentleman's words as nearly as possible: "I exhaust the air in the cabinet to an amount causing a pressure on the outside of the cabinet of about three to five pounds to the square inch (an equivalent of a depression of six to ten inches of the mercury), and direct the patient if he become nervous to open the stop-cock *very slightly*, so that the outside air may enter enough to reassure him, and then let him sit in the rarefied air for a certain length of time, and at the end of the sitting make him take one or two deep inspirations to expand his lungs, opening the stop-cock a little at the same time, the end being in the mouth." From this description it will be seen that his method resembles more those previously spoken of, in which the patient merely sits in a rarefied atmosphere for a given time. No attempt is made to breathe in and out as in Dr. Williams's cabinet; indeed, this would be impossible with the great amount of rarefaction used, for the force of air rushing in through the wide open stop-cock would severely injure the patient; moreover, as I said before, no attempt is made to combine the spray with his apparatus. So it will be seen how essentially the two methods differ at the outset, to say nothing of the fact that while in the one case we are dealing with a scientifically educated physician, in the other we come in contact with one who professes to "diagnosicate his case by his eye"; who "never auscults nor percusses his patients nowadays," and who "draws the corruption out through the skin," etc. etc.

I have endeavored to give the important facts relating to Dr. Williams's apparatus, and to show how it differs from other methods of treatment as far as I have been able to learn of them by reading or by personal observation. My object will be accomplished if the paper shall excite discussion; and I trust if there is any one present who knows of methods of treatment resembling those of which I have spoken, he will speak of them to the Society this evening.

A SOUTHERN contemporary mentions a lady who summoned a physician to her husband, and told him to bring his "urethra" with him. He of course complied, but also carried a catheter, which proved to be what was wanted.

## Reports of Societies.

### THE SEVENTH ANNUAL MEETING OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.<sup>1</sup>

HELD AT DETROIT JUNE 24-26, 1885.

THE regular session of the second morning was opened by the reading by title of a "Case of Sub-mucous Laryngeal Hemorrhage, complicated by Cyst," by DR. FRANK L. IVES, of New York.

DR. HARRISON ALLEN, of Philadelphia, then read a paper on

#### THE GALVANO-CAUTERY IN LARYNGOLOGICAL PRACTICE.

with which he presented a new and original can-tery snare. The snare was based upon the principle of the Jarvis instrument, except that a platinum wire was used, and arrangements for attachment with the battery, so that the snare might be used either cold or with the galvano-cautery. Some interesting principles in the use of the instrument were explained.

A short and interesting paper on "The Principles involved in the Construction of Spray Tubes," by DR. ANDREW H. SMITH, of New York, was then read by the Secretary.

A number of important instruments were next presented. The exhibition of improved electric lights and galvano-cauteries was by far the most important ever presented to the Association; and the advances made in this department during the past year were shown to be of extraordinary significance.

DR. COMBES presented an excellent accumulator, manufactured in Philadelphia, together with an electrical laryngoscope and other attachments.

DR. DE BROS presented a new powder-blower combined with a laryngeal mirror.

DR. ASCEN presented two instruments: An osteo-tome for the removal of exostoses in the nasal passages, and a modification of the Jarvis snare, in which the wire was secured by a clamp instead of being wound around a pin.

DR. HOOPER showed the electric lamp and pocket accumulator as perfected by Dr. Felix Semon and Mr. Arthur Vesey, manufactured by J. Weiss & Son, London.

DR. SEILER and DR. JARVIS also presented instruments.

The session of the afternoon was opened by the reading of an elaborate and highly interesting paper by DR. E. FLETCHER INGALS, of Chicago, entitled

#### LEUCOPLAKIA BUCCALIS ET LINGULÆ, OR ECTHYOSIS LINGULÆ: SUCCESSFUL TREATMENT BY THE GALVANO-CAUTERY.

During the past year it had been the author's good fortune to cure a case of the rare and intractable disease which formed the subject of this paper. The disease had been recognized but a short time, very little had been written upon it, and that little was involved in what at first seemed inextricable confusion. This because several different affections had been confounded and described under the same name. Thus "smoker's patches," the condition found in old glass-blowers termed "professional patches," psoriasis linguæ, and various manifesta-

tions of syphilis, having been considered by different authors as true leucoplakia or as one of its phases. Professor Ingals defined leucoplakia buccalis as a chronic affection of the buccal mucous membrane, characterized by thickening of the epithelium and the formation of white, opaline, elevated patches, which usually become fissured and painful, and after continuing for a long time are likely to terminate in epithelioma.

A full history of the disease was given, with copious references.

The anatomical characters, causation, clinical history, and diagnosis were thoroughly considered. As to prognosis, the duration of the disease is uncertain. Two cases were referred to in which cancer supervened in less than six months. Among the indications that leucoplakia is passing into epithelioma were non-inflammatory enlargements of the lymphatic glands, with exfoliation of the thicker portions of the patch, the formation of an ulcer, the supervention of sharp pains, salivation, and at length induration of the subjacent tissue; finally, great swelling in the region of the jaw is likely to occur, and death takes place from exhaustion.

*Treatment.*—In cases of leucoplakia all sources of irritation, particularly those resulting from the use of alcohol, should at once be removed, and if the digestive organs are deranged, as is frequently the case, they should receive proper attention. Aside from these measures most authorities believe treatment of little or no avail.

In the case reported in the paper internal remedies were useless, and local applications of tincture of iodine, nitrate of silver, and the acid nitrate of mercury greatly increased the patient's suffering, and would doubtless have aggravated the disease had they been persisted in. As soon, however, as the actual galvano-cautery was applied relief from all pain was obtained, and by a persistent and careful use of it the disease was eradicated. From a study of the literature of the subject, and from his own experience, the author had arrived at the following conclusions: First, leucoplakia buccalis is an idiopathic disease, distinct from psoriasis, "smoker's patches," and syphilis. It is largely confined to men past middle life, but occasionally occurs in women. Second, the disease is so commonly found in inveterate smokers that the abuse of tobacco may be fairly claimed as an exciting cause, though cases occur where tobacco has never been used. Third, the affection is chronic, and finally terminates, in a majority of cases, in epithelioma. Fourth, internal treatment and the local application of sedative, stimulant, or caustic drugs is in nearly all cases either useless or injurious, and the latter are sometimes disastrous by hastening the development of epithelioma. Fifth, the actual cautery, or the galvano-cautery, will probably enable us to cure many cases, if they are treated sufficiently early; provided it is applied to only a small spot at each sitting and carefully, so as not to destroy the healthy tissue beneath the changed epithelium.

The author's case was then recited in detail and a complete bibliography of the subject appended.

In the unanimous opinion of the Association the paper of Dr. Ingals was a timely and important

<sup>1</sup> Continued from p. 57.

communication, which could not fail to excite widespread interest.

Dr. R. P. LINCOLN, of New York, contributed a paper in which he reported

A CASE OF MELANO-SARCOMA OF THE NOSE CURED BY GALVANO-CAUTERIZATION.

A little over two years ago patient first noticed an obstruction to free respiration in the right nostril. This was followed by continual muco-purulent blood-stained discharge. Her general health at this time was good; there was little or no pain. Six months later this nostril became completely occluded. The growth was then removed and pronounced upon microscopic examination to be cancerous. Two months later the former symptoms reappeared and continued to increase for eight months, when the first operation was again repeated. In the course of four months afterward the tumor increased very rapidly, when the patient placed herself in the hands of a so-called "cancer doctor." The patient came under the observation of Dr. Lincoln, in November, 1884. At this time the right side of the nose, extending to the inner canthus of the eye, showed a fulness amounting to about four times the size of the left side of the nose. The lower half of its ala was wanting, and there protruded from the right nostril for about half an inch a dark-colored, fleshy mass, which completely filled it. This was attached to the outer margin of the nostril as well as to its floor. A plum-colored discharge flowed constantly from the nostril, and the lightest touch by a probe upon the mass excited hemorrhage. Exploration showed the tumor to grow from the inferior and middle turbinated bones and from the floor of the nostril for a distance of two inches and a half. The septum was free. The tumor protruded in the post-nasal cavity, occupying about half of it. Its removal was effected by means of the galvano-caustic écraseur and a subsequent cauterization of points of attachment. Great pains were taken to make the cauterization complete and thus secure the entire removal of diseased tissue. Hemorrhage was inconsiderable. A disinfectant solution was used for about a week after the operation. The patient was allowed to return home two weeks after the operation. On May 27, 1885, the patient having returned at intervals of one or two months since the operation, careful examination failed to reveal the slightest recurrence of the disease. A microscopic examination of the tumor made by Dr. Frank Ferguson, of the Pathological Department of the New York Hospital, identified the tumor as a true melanotic sarcoma.

In the next paper, Dr. J. O. ROE, of Rochester, New York, presented the history of an extremely interesting tumor of the nasal cavity, which the microscope proved to be an angioma. The subject in general was thoroughly discussed by the writer and a full bibliography of the subject furnished.

Dr. MACKENZIE remarked that certain cases of angiomatous nasal growths might be referred to the category of hypertrophic enlargement of the turbinated bodies.

Dr. J. W. ROBERTSON, of Detroit, then read a paper on

DEFORMITIES OF THE NOSE AS A FACTOR IN NASAL CATARRH.

He inquired: (1) What are the causes of the large number of deformed noses? (2) At what age do these deviations from the normal take place? (3) In what way do these deformities produce catarrhal diseases? and (4) how can these abnormal conditions be prevented?

The author then related statistics from which it appeared that a large percentage of deformities of the nose were directly due to injuries received, syphilis, serofula, tuberculosis, and allied diseases, which caused necrosis, ulceration, and also congenital improper development. The deviations from the normal took place, according to statistics given by Dr. Robertson, in large proportion between the ages of ten and twenty years, either through the receipt of injury or improper development due to malnutrition. These deformities, through blocking up of secretions, a local malnutrition, or a too free entrance of air, may give rise to catarrh. These abnormal conditions might be avoided by understanding that the time to prevent catarrh and its concomitant diseases is during the growing period of childhood. Deformities due to traumatism, such as fractures and dislocations, are more easily relieved in the young, and should be attended with as much care as corresponding injuries in a larger bone. In cases of syphilitic and serofulous disease, where the secretions are profuse and inclined to adhere to the mucous membrane, the constant irritation should be relieved by appropriate measures. Care as to hygienic surroundings, and an attempt by proper treatment and feeding to develop, if possible, the bony structure of the nose in children, should be observed.

Dr. MACKENZIE referred to the custom of the ancient Persians with reference to securing symmetry of the nasal chamber in children of the royal blood.

Dr. CLARENCE C. RICE, of New York, then read a paper on

INFLAMMATORY ADHESIONS OF THE SOFT PALATE TO THE WALL OF THE PHARYNX.

The author recognized the lack of success which heretofore has characterized the efforts of most operators for the relief of this condition. In considering the prognosis such cases should be divided into two classes: first, where the sole lesion is the adhesion of the soft palate to the walls of the pharynx, and second, where, in addition to this, extensive cicatrization has narrowed the normal cavity of the naso-pharynx. The author paid a high tribute to the skill and success of the late Dr. Elsberg in the treatment of these cases, and closed the paper with the relation of an original case in which he had operated with success.

The session of Friday, June 26th, was opened by a paper on

ALIMENTATION IN LARYNGEAL PHTHISIS.

by Dr. BEVERLEY ROBINSON, of New York, which was read by the Secretary. The writer explained that three methods of treatment were in vogue for the alimentation of such patients: first, the method

of superalimentation, advocated by DeBove and others; second, the method by means of a tube of small calibre passed a short distance into the œsophagus, and proposed by Delavan; and third, the method by rectal enemata. Each of these methods he explained somewhat in detail, and opposed against them certain objections, fortifying his conclusions by the quotation of several original cases. He strongly advocated the application to the ulcerated parts of cocaine, which greatly diminished the dysphagia and enabled the patient to swallow with comparative ease. Without the use of a local anæsthetic, however, such as cocaine, it was admitted that in some cases of laryngeal phthisis when deglutition was otherwise painful, the patient might be sustained for months by means of injections of food into the stomach through an œsophageal tube. Moreover, that, in those severe cases in which the passage of the œsophageal tube occasioned considerable pain, dyspnea, or nervous exhaustion, and despite the previous local use of cocaine, recourse might be had, as heretofore, to the use of nutrient enemata judiciously managed.

DR. COHEN spoke favorably of the use of the small tube passed only part way into the œsophagus, which method he had used with good results.

DR. DELAVAN also defended the method on the ground that by the use of the tube ulcerated parts were protected from irritation; that the use of cocaine was in many cases unsatisfactory; that the method, although not uniformly successful, would be found of value in a large number of these distressing cases, and objected to its condemnation by Dr. Robinson on the slender basis of two unsuccessful cases. As to the point raised by Dr. Robinson that the method had been described by Dr. Frank Donaldson in 1883, he desired to call the Association's attention to the fact that he had presented a full description of it in his candidate's thesis for the American Laryngological Association, submitted to the Council of the Association in the early part of 1880.

In the absence of Dr. F. H. Bosworth, of New York, his paper, "An Additional Note on the Therapeutic Action of Cocaine," was read by title.

A paper upon "Personal Experience with some Recent Additions to the *Materia Medica* of Laryngology," by Dr. J. SOLIS-COEN, of Philadelphia, was next presented. In this the author's experience with several new drugs was related and many original and valuable suggestions communicated.

A paper entitled "A Case of Membranous Nasal Catarrh," in the absence of the author, Dr. G. W. MAJOR, of Montreal, was read by title.

The literary exercises of the session were concluded by a discussion on the efficacy of mild measures in the treatment of so-called nasal and nasopharyngeal catarrh, which was opened by Dr. COHEN, who argued that less radical measures than those now in popular use were frequently indicated, and suggested the importance of distinguishing between true hypertrophy and mere turgescence of the nasal mucous membrane. He advocated pressure as an efficient means for the reduction of turgescence, and suggested an ingenious method by which equitable pressure could be employed. This was the introduction into the nostril

of a laminaria tent, cut down until its cylindrical form had been reduced to a thin, flattened oval; this in proportion to the size of the nasal cavity. The tent was to be introduced into the nostril and, moistened by the nasal secretions, allowed to swell; the patient meanwhile being directed to prevent the tent from swelling to such a degree that it could not easily be removed.

The discussion was participated in by Drs. DEBLOIS, COOPER, ASCH, RICE, MACKENZIE, and SHERLY, and the views expressed by Dr. COHEN very cordially received. A vote of thanks was made by the Association to the Detroit Medical and Library Association, to the physicians of Detroit, and to the members of the Detroit press, from all of whom many courtesies had been received.

The ballot for officers resulted in the election of Dr. Harrison Allen, of Philadelphia, President; Dr. H. A. Johnson, of Chicago, Vice-president; Dr. George W. Major, of Montreal, Second Vice-president; Dr. D. Bryson Delavan, of New York, Secretary and Treasurer; Dr. Thomas R. French, of Brooklyn, Librarian, and Dr. J. Solis-Cohen, of Philadelphia, Member of Council.

The next annual meeting will be held in the city of Philadelphia, on the last Thursday in May, 1886.

#### SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

APRIL 8, 1885. The meeting was called to order at 8 o'clock. The Chairman being absent, on motion of Dr. Vincent Y. Bowditch, Dr. JAMES C. WHITE was chosen chairman, *pro tem*.

The records of the last meeting were presented in abstract and approved.

The first business of the evening was the report of the committee appointed at the last meeting for the purpose of suggesting the means of defraying the necessary expenses of the Clinical Section. Dr. VINCENT Y. BOWDITCH presented the report, and stated that there was a small but continuous outlay for the purposes of the Section, for which no provision had ever been made by the members.

The sum at present expended in this way during the past three years was about twenty-five dollars; and it was proposed that the members of the Section contribute as they might feel disposed toward the liquidation of this amount. A paper was passed about the hall, and the amount of money needed was very soon subscribed.

Dr. F. F. DOUGGETT then read a paper entitled

METALLIC POISONING FROM CANNED FOODS. WITH A REPORT OF SIX CASES OF POISONING FROM CANNED TOMATOES.<sup>1</sup>

PROFESSOR HILLS stated that the reader had given an impartial *résumé* of the literature of the subject, as it has appeared in the medical journals of the past few years. He criticized, however, the prevalent practice of attributing the symptoms which

<sup>1</sup> See p. 49.

sometimes follow the ingestion of tinned foods to metallic compounds, without first ascertaining that the article ingested actually contains such compounds. It is not sufficient, moreover, to show that the food contains an unknown quantity of some metal. A quantity sufficient to account for the symptoms must be demonstrated before one is justified in attributing the symptoms to metallic poisoning. Symptoms resembling those of irritant poisoning not infrequently follow the ingestion of food which has not been preserved in tins, and in which chemical analysis has failed to disclose any irritant poison. Cases are also recorded in which tinned foods, free from metallic salts, have given rise to similar symptoms. In these cases the symptoms could not have been caused by metallic irritants; and the speaker believed this to be true of a large majority of the reported cases of poisoning from tinned foods.

Two facts are well established with reference to these foods: First, they frequently contain traces of certain metals; they usually contain tin; not infrequently zinc or lead. Second, symptoms resembling those of acute irritant poisoning, and even death, have followed their ingestion. It has not been proved in any authenticated case, so far as the speaker could remember, that the symptoms have been caused by the metallic impurity.

It is important to bear in mind that the quantity of tin, lead, or zinc which a can of food contains is very small. The quantity of tin, when present, usually ranges from a few one hundredths of a grain to one grain per pound, rarely approaching, however, the higher figure. These amounts are not likely to give rise to symptoms of acute poisoning, though, it is true, but little is known regarding the poisonous action of tin compounds, if we except the chlorides and the oxide. The speaker believed, however, that a quantity sufficient to produce harm is rarely present. If present, he believed that it would be recognized by its taste, and the food thus contaminated be rejected as unpalatable. Such cases, so far as there is any evidence, are rare. Lead in tinned foods is derived either from the tin plate or from the solder. The quantity present in foods thus containing lead is too small to give rise to symptoms of acute poisoning. Zinc is frequently detected in tinned foods. Its presence is attributable to the use of the chloride of zinc solution as a soldering fluid. The speaker could not recall any cases in which a determination of the amount present had been made. He did not, however, deny the possibility of tinned foods, at times, containing a sufficient amount of chloride of zinc to cause symptoms of acute poisoning, or the possibility of such symptoms having been caused by this substance. He objected to attributing the symptoms in any case to chloride of zinc without a chemical analysis. The probability of the occurrence of such cases must be slight, since the solution employed is dilute, and a small amount only is used on each can. Through the carelessness of workmen, however, a quantity sufficient to produce symptoms might find its way into the food, but food thus contaminated would be rejected by reason of its disagreeable taste. It has been suggested that the excess of hydrochloric acid in the soldering solution may act upon the tin,

forming the poisonous chloride of tin. If the soldering solution is properly prepared, and an excess is avoided in soldering the cans, it is not probable that a quantity sufficient to produce harm will be formed. If present in injurious amount it would undoubtedly be recognized by its taste. On the whole, these cases of acute poisoning as a result of metallic impurities in canned goods must be very rare. All the cases thus far reported are based on insufficient evidence.

To what, then, are the symptoms to be attributed? Doubtless, in many cases, to idiosyncrasy on the part of the patient; in some cases perhaps to the decomposition of food. It is possible that in certain cases poisonous ptomaines may have been developed in the food. Finally, it must be borne in mind that cases of subacute poisoning may result from the use of copper utensils, or utensils containing lead, for the preparation of the food. Cases of poisoning from these causes are no more liable to occur with tinned foods than with other foods if proper care is exercised. The speaker thought that the principal danger to be apprehended from the use of canned foods was that of chronic lead-poisoning. Such cases have been reported and are always to be feared when these foods are used continuously for a considerable time. They are now used very largely in this way on shipboard and in the army. It is always a wise precaution to remove the food from the can as soon as the latter is opened, since the solution of the tin or lead may be favored by the presence of air. Analyses suggest the probability that time may be a factor in the solution of tin and lead. Foods which have been put up two or three years have been found to contain more of these metals than those put up more recently. It is advisable therefore to avoid old cans.

DR. VINCENT Y. BOWDITCH remarked that he recently had the opportunity to visit the office of the Board of Health in New York, and that he was there shown a large quantity of food preserved in tin cans, which had been found to contain alarming amounts of copper and lead. The same varieties of fruit were afterward preserved in glass jars but were still found to contain copper. It was supposed that the metallic contamination was derived from the employment of copper utensils in the process of preserving the fruits.

DR. DOUGGETT maintained that as physicians we should regard any article of food as dangerous, when well-marked signs of deleterious action are observed to follow the ingestion of this substance. The chemist may not be able to detect all the injurious compounds which may either exist in or be formed in the various articles of food which are preserved in cans for human consumption. It would seem to be the duty of the physician to pronounce such articles of food to be poisonous even if no poison be detected by analysis.

PROFESSOR HUIS objected to the position assumed by the reader. If sickness follow the ingestion of any article of food and chemical analysis demonstrates that no corresponding metallic contamination exist in the particular food, it is surely better to know that this is so than to blindly consider the sickness to be occasioned by the presence

of a metallic poison in the contents of the can. If no other good result should follow, it would surely direct the attention of scientific people to the discovery of some other unsuspected cause of the sickness.

DR. BLODGETT observed that several cases of supposed poisoning from canned foods had recently been reported in the English journals, and that several important hints had been given as to the character of the contents of the can. The fact that the ends of the can are crowded outward, or *bulged*, is an indication that decomposition of the contained food may have occurred. The presence of two punctures in the cover of the can, would often indicate that the food as originally put up was not properly prepared, but underwent a process of chemical decomposition accompanied by the formation of gases which caused the ends of the can to be projected outward. The top of the can is then perforated a second time and the gas allowed to escape and a second drop of solder is then applied to the opening, thus showing conclusively that the contents of the can were not perfectly preserved when first sealed.

In England it has been found that cans of improper food are often stripped of their paper wrapper and that the second puncture is then made upon the side of the can instead of at the end, and on replacing the wrapper upon the can, the second puncture cannot be detected.

PROFESSOR HILLS stated that the cases reported by Dr. Johnson before the New York Medico-legal Society were not proved, and should not be considered. The statements of Dr. Johnson rest upon pure assumption, and are not trustworthy. The flux that is commonly used is a saturated solution of zinc in chlorhydric acid; and no free acid exists by which any deleterious effect could be produced.

It is desirable that, in cases of suspected poisoning from canned goods, a portion of the contents of the *identical can*, which is supposed to contain the poisonous substance, should at once be submitted for chemical analysis. If, under these circumstances, poisonous ingredients or products are detected in appropriate amount, the claim against the foods might reasonably be entertained. Until this can be demonstrated, however, we must in most cases seek other causes for the unwholesome effects occasionally noticed after partaking of tinned or canned goods as articles of food.

DR. WHITT asked how long the family had subsisted on tomatoes before symptoms of poisoning were observed.

DR. DOGGETT stated that tomatoes had been almost the sole and continuous article of food for two months previous to the occurrence of sickness.

DR. WHITT said that it would be quite improbable that two families should take water from the same supply-pipe and that lead-poisoning should occur in only one. The water must be excluded as the source of poisoning. We frequently notice that contaminated water will produce poisoning in some members of a family and not in others; but the freedom of one entire family from a disease which became general in another using the same water-service would seem to indicate that the water-supply was not the source of the poison.

DR. DOGGETT, in conclusion, remarked that the attempt had been made to draw up the paper impartially and to exclude all evidence which might be called sensational. As stated in the paper, both with regard to the writer's cases and the reported cases drawn from all sources, the attempt was made to establish them on medical and circumstantial evidences and not on chemical, for in no case, so far as known, has a quantity of metallic poison been found in a can sufficient to produce death or dangerous symptoms. In regard to Dr. Hills's inference that the cases of the writer were not proved to be cases of metallic poisoning, Dr. Doggett replied that from the chemist's standpoint they were not so proved, nor had the attempt been made to prove them, but from the physician's standpoint, relying on the medical and circumstantial evidence, cases I., II., and VII. were certainly cases of metallic poisoning from canned tomatoes, and he presumed Dr. Hills would agree with him in this statement, chemical evidence apart. It would have been an interesting fact to the physician as well as to the chemist to have known how many grains or fractions of a grain of lead were present in the cans consumed, but in the absence of this information the fact of poisoning remains, and though Dr. Hills has said that as a chemist one should not believe it until he had demonstrated chemically the presence and amount of lead in the cans eaten, Dr. Doggett does not believe that even he, in light of the medical and circumstantial evidence given above, would have allowed the family to continue eating the tomatoes. As proved in this sense the cases reported should have weight in every candid mind. The danger most of us recognize as a slight one, but it is none the less a real one, and the writer believes that statements from chemists like Professor Atfield that "the public has not the faintest cause of alarm respecting poisoning from lead or tin in canned foods," are likely to do harm, for, besides making the consumer less careful in selecting the canned foods, it will make the producer more careless in the preparation.

DR. T. A. DE BLOIS read a paper on

#### TWO CASES OF RETRO-PHARYNGEAL ABSCESS.<sup>1</sup>

DR. HOOPER spoke of the extreme rarity of the disease, and stated that during the five years he had been connected with the Throat Department at the Massachusetts General Hospital he had seen but a single case. This was in a baby brought in from the surgeon's room by Dr. A. T. Cabot. It was under Dr. Cabot's treatment and made a good recovery. With reference to diagnosis, Dr. Hooper mentioned a remarkable case that he had operated upon when a student in Professor Schrötter's clinic, in Vienna, thinking that he had to deal with a retro-pharyngeal abscess, but which turned out to be something entirely different. The patient was an adult and presented all the subjective and objective symptoms of the disease. No pus followed the incision into the swelling, neither did it diminish in size. The patient had a small goitre, and Professor Schrötter finally determined that the tumor, which was situated low down in the pharynx, was a lobe of the

<sup>1</sup>See p. 53.

thyroid gland which had grown round to that position.

Dr. G. W. GALVIN said that he had nothing to add to the description given by the reader of the appearance of the case or of its treatment. It is quite easy to distinguish this disease from tonsillitis. A similar enlargement in or about the tonsil would prevent the patient from opening the mouth.

Dr. BLODGETT mentioned one case within his observation in which the nature of the disease was not fully recognized, and treatment was mainly expectant. After a period of four days the abscess suddenly opened spontaneously and a copious discharge of pus occurred, from which the patient was quickly suffocated and immediately died. Dr. Blodgett thought that too much stress could not be put upon the necessity of quickly inverting the patient so as to allow the contents of the abscess to escape from the mouth, as the amount of pus was frequently much greater than could have been anticipated and the danger of immediate death from suffocation is always present. It would seem that in hardly another form of surgical disease was timely and judicious operative interference more urgently demanded than in cases of retro-pharyngeal abscess.

Dr. Blodgett asked if necrosis of the vertebra or kyphotic deformity were ever produced by a purulent process located in immediate contact with the vertebral column.

Dr. DE BLOIS replied that this has not been observed, owing doubtless to the acute character of the disease as well as to the fact that some form of acute meningeal inflammation would probably be induced by the invasion of the vertebral column in the rapid manner in which this would occur from a pharyngeal process, and that a fatal result would almost of necessity ensue before necrosis or exfoliation of the bony tissues could occur.

#### NEW SPRAY-PRODUCING INSTRUMENTS.

A new pattern of spray-producing instruments was exhibited to the section, in which but one tube is employed, thus seemingly escaping the complication of two tubes of small calibre, and in which the flask containing the medicament was also the reservoir for the compressed air. The instruments seemed to work quite satisfactorily, although there seemed to be a question as to the durability of the tube owing to the fact that all the medicament is to be projected through the entire length of the tube.

Adjourned at 9:50 o'clock.

#### MASSACHUSETTS MEDICAL SOCIETY.

##### ANNUAL CONFERENCE OF CENSORS.

TUESDAY, JUNE 9, 1885.

The delegates from the various district societies met, according to appointment, at 19 Boylston Place, at 2:30 p.m.

The meeting was called to order at 2:45 by Dr. ALBERT N. BLODGETT, Clerk.

On motion of Dr. F. C. Shattuck, of Suffolk, Dr. JOHN CROWELL, of Essex, North District, was elected Chairman.

The roll-call by districts was answered by fifteen

delegates accredited to the boards of censors of the various district societies.

The records of the last meeting were read and approved.

The following communication from the Board of Councilors was read by the Clerk and ordered to be placed on file:—

ROXBURY, MASS., February 5, 1885.  
A. N. BLODGETT, M.D., Chairman of Committee of General Censors' Meeting.

DEAR SIR, — I have the honor to inform you that, at a meeting of the Councilors, held on the 11th inst., a communication from the Committee of which you were Chairman was read. It was voted that the Committee be informed that the Councilors received the communication and express sympathy with the efforts of the Censors toward securing uniformity in the examination of candidates.

Yours truly, F. W. Goss,  
*Recording Secretary.*

The CHAIRMAN in an appropriate manner presented the business of the present conference. He stated that, at a former meeting of this body at which he had the honor to be chosen chairman, the subject of uniformity of examinations for the admission of candidates by the various district societies of the Commonwealth was the principal topic of discussion and would no doubt claim attention at this meeting. At the former time the reports of the delegates showed a great diversity of methods in examination, as well as considerable variation in the standard adopted by the several boards of censors, which had certainly been changed for the better in some ways, as he could report on behalf of his own Society. The subject was then declared open for discussion.

Dr. SHATTUCK, of Suffolk, stated that the question seemed to be really one of simple conformity to the regulations already made and provided by the State Society for the guidance of the officers of the State Society in the admission of new members to that body. Some of the district boards have advocated a change in the existing laws so as to make their enforcement more severe, and thereby constrain the district boards to a more rigorous form of examination. The censors of Suffolk consider the present provisions of the by-laws as in every way ample and sufficient, and have never advocated a change, nor do they believe that additional legislation is either expedient or desirable.

Dr. CORNUM, of Hampshire, said that his Society has in the past been lax in its system of examination, but he stated that he was to-day able to say that they had adopted a written and an oral system of examination, and the Society desires to go on record as complying with the by-laws of the State Society in this respect. Dr. Cornum also heartily endorsed the views of the delegate from Suffolk as to the inexpediency of further legislation by the State Society, but would use every endeavor to comply with the requirements of the existing laws.

Dr. DOLLE, of Hampden, asked what action this body can take which shall compel the enforcement of any regulation for the guidance of the district boards of censors.

Dr. SHATTUCK, of Suffolk, stated that this is

simply a meeting for conference and consultation. We have no power to enforce any particular system upon the boards of censors, and no desire, in any way, to interfere with the doings of the various boards. We meet only for enlightenment and counsel. The good effect of these meetings is already to be observed in the greater uniformity of method which now prevails in the State in comparison with the practices of a few years ago.

Dr. ENXET, of Norfolk, thought it very useful for our mutual information to know what the censors were doing in the various parts of the State.

Dr. J. B. RICH, of Worcester District, thought that a just account of the present methods in that district has not been given to the censors at large. The examination is now both oral and written. The credentials of the candidate are carefully examined and a record in the handwriting of the candidate is preserved in a book kept for that purpose. The oral examination first takes place and at another time the candidate is given a list of written or printed questions in order to further ascertain his fitness for admission. Few changes are made in the composition of the Board of Censors in Worcester District and each censor examines upon a special branch. The examination papers are marked on a scale of 100, and the candidate is accepted or rejected according to the result of the examination thus conducted.

It is considered that the by-laws are now complied with in this district. It is evident to all that the details of any system of examination must be left to the district boards, but the general plan in the various portions of the State is plainly becoming nearer to uniformity of examination than seemed possible a few years ago.

Dr. HISE, of Essex North, asked how long this plan had been carried out in Worcester District.

Dr. RICH stated that printed questions were first used last year. Written questions have been in use for five years, but the influence of these conferences led to the adoption of printed questions.

Dr. HISE said: "As censor for Essex North District, I am sorry to say that our district has no method of examination. We have no written examination at all. I sincerely hope that this will not long be the case, and I announce that, before another meeting of this conference, our district will come into line with a system of examinations which shall conform to the requirements of the State Society and the views of this meeting."

Dr. ENXET, of Norfolk, stated that he did not know how Norfolk District Society is registered, but that there is no written examination of candidates for admission to the society in that district.

Dr. E. A. DYER, of Franklin District, said that in this district it has been customary to conduct the examination entirely orally, and things have been very loosely managed, but last year a written examination was introduced though the influence emanating from this conference, and will form a prominent feature of all future examinations in this district.

Dr. EGGLEY, of Middlesex South District, stated that formerly the written examination constituted but

a small part of the examination in that district, but it has been recently much increased, and the examination has become much more satisfactory.

Three questions are sent by each censor to the President of the Board who causes all the questions to be written in books, which are distributed to the candidates. The answers are written in books also and are filed for reference.

Dr. BLODGETT, of Suffolk, spoke of the encouraging results which have attended the labors of this conference in past years, and thought that it was important that the censors should come together at times for comparison of results and consultation. A few years ago much opposition was experienced from several of the district boards, who seemed to fear that the conference was endeavoring to usurp the rights of the censors, but this feeling is now no longer apparent, and the censors of the entire State are working with a unanimity and harmony never before possible. It is to be hoped that these meetings may become a permanent feature of the annual proceedings of the State Society. Dr. Blodgett urged the censors present to endeavor to secure the attendance of delegates from every district board in the State that the conference might be made as cosmopolitan as possible and represent the views of the censors of the entire Commonwealth.

On motion of Dr. SHATTUCK, of Suffolk, it was Voted, That this meeting learns with pleasure the increasing uniformity with the by-laws as regards the method of examinations of candidates by the censors, and hopes to hear next year a report of further progress.

Dr. COOPER, of Hampshire, said that he should have opposed any other motion than the one just presented by the delegate from Suffolk. The censors of other district societies have suspected that the censors of Suffolk were endeavoring to control the action of the censors throughout the State. He could cheerfully vote for the present resolution but would oppose any motion which should seek to interfere with the action of the censors in other districts.

Dr. SHATTUCK disclaimed for himself and for the district which he represented any intention, in any way, to control or influence the action of the district boards. The sole effort of this conference should be to seek to do justice in examination of candidates in all parts of the State. The Suffolk censors do not consider further legislation either necessary or advantageous, but would seek to secure the compliance of the district boards with the by-laws already made, believing that they are calculated to accomplish all that is possible to hope from any legislative action. Dr. Shattuck said that he was glad the delegate from Hampshire had spoken with such candor and frankness, and looked upon this freedom of discussion as on one the more important benefits of these meetings.

On motion of Dr. BLODGETT, of Suffolk, it was Voted, That the delegates here assembled be requested to report the doings of this conference to their respective district boards of censors, and that the censors of each district be urged to send a full delegation to take part in its future meetings.

Voted to adjourn.

# Medical and Surgical Journal.

THURSDAY, JULY 16, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

## SUPRA-PUBIC LITHOTOMY, EPICYSTOTOMY, ETC.

THE operation of exposing and opening the bladder above the symphysis pubis, for the removal of stone, has come so prominently into favor again of late years, and its field of possible usefulness has been so widely extended by the additional advantages for the removal of tumors, and the radical treatment of hypertrophied prostate so approached, that it may not prove uninteresting to our readers to have laid before them a short sketch of the history of an operation which seems likely to take a new lease of life after falling almost completely into disfavor, and of the reasons which have led to its becoming a more popular procedure.

The supra-pubic operation properly had its origin in the hands of Pierre Franco, who performed it with success in Lausanne, about 1560. Franco, in this case, rendered the extraction of the stone more easy by pushing it upward by two fingers in the rectum. The case of Jean Doot may be quoted among the early operations as a matter of curiosity, he having removed a stone from his own bladder through an incision above the pubes, made with a shoemaker's knife.

In 1581 Rousset recommended the injection of the bladder with water, with a view to elevating it above the symphysis, previous to incising it. Piètre, in 1635, tried to accomplish the same result by the introduction of a sound into the bladder.

The operation was not much heard of until Douglass and Cheselden, almost a century later, revived it, both practising it successfully several times. It now was more frequently performed, meeting with varying success and failure, until it came into the hands of Frère Côme, who, in 1799, had operated one hundred times with only nineteen deaths. Perineal section was practised in combination with the high cut by Côme and by Serres before him.

In our century many surgeons have done the operation, among them Dupuytren, Souberbielle, Sir Everard Home, Leroy d'Étiolles, Nélaton,

Civiale, etc. etc., but it may be said that throughout this time, until of recent years, the operation has steadily lost ground.

Up to six or eight years ago but little change was made in the technique. Since then three notable advances have again placed it in the category of favorite surgical operations; these steps are: (1) Antiseptics; (2) Vesical suture or drainage; (3) Combined vesical injection and rectal ballooning.

Of antiseptics little need be said. Any one of the favorite antiseptic routines may be associated with the operation.

Attempts at vesical suture date far back. In more recent times Lotzbeck (1838) used it in the human subject. And Tissière and Baddon made some experiments in regard to it in 1853. Since then it has been more or less employed, especially in Germany, by Uitzmann, Dittel, and others. Heath, Rivington, Willet, and others have used the suture in England for ruptured bladders; and ovariologists, both in Europe and America, have had recourse to it with marked success after accidentally incising the bladder during the operation for the removal of a cyst. It should be noted that the fortunate issue in these latter cases, however, is probably in great part due to the fact that the operators have, in the majority of instances, had to do with bladders previously healthy, which have not been the seat of cystitis or of foreign growths, with resulting thickening of their walls and consequent indisposition to heal. In France the bladder suture has been for the most part discarded, and the drainage of Perier (to be described subsequently) substituted.

The union of the vesical wound has been undertaken in three principal ways: (1) The continuous Lembert suture. (2) The single line of interrupted suture. (3) And that which has become the favorite as being the safest—the double line of interrupted suture. In this last method the first line is inserted close to the wound without including the mucous membrane; the second line passes through the serous surfaces only, alternating with the first, and approximating the surfaces further out; the adhesive inflammation taking place between these layers being the important element in the union of the wound.

The sutures should be of carbolized silk, and not of catgut, as experience has shown that the latter does not hold long enough to secure union. Silver wire has also been employed, the sutures being allowed to remain in the tissues. This procedure has also its advocates, but the preponderance of opinion favors carbolized silk cut short and left to take care of itself.

Whatever the material and whatever the method, it must be confessed that thus far the wound has leaked before union was complete in the majority of cases, although some are recorded in which a first intention was obtained. Perfection of bladder

suture, therefore, has not been reached, and consequently this method has been abandoned by some surgeons.

Villeneuve, of Lyons, in a recent monograph upon the subject of supra-pubic lithotomy (1883), concludes upon this head: "The vesical suture ought not to be used, but remains always the ideal to be sought, which, if realized, will place, owing to first intention of the bladder wound, the superiority of this operation beyond question."

Before the London International Congress, in 1881, Vincent reported favorably upon the suture, basing his conclusions chiefly, however, upon experiments with rupture of the bladder in dogs and rabbits.

The conclusions reached were as follows:—

(1) "Vesical suture applied immediately after injury to the bladder, and properly applied, almost always succeeds." (2) "Laparotomy and vesical suture succeed more often if undertaken within ten hours after the injury has occurred." (3) "That, in intra-peritoneal ruptures of the bladder followed by extravasation of urine into the peritoneal cavity, one can save the patient almost certainly by proceeding immediately to laparotomy and bladder suture." . . . (4) "The possibility of spontaneous bladder cicatrization has been demonstrated, but is not the rule." (5) "In view of the great fatality of such wounds when left to themselves, one should have recourse always and as early as possible to the operation."

Stein has recently urged the application of the bladder suture in a strong article published in *The Annals of Anatomy and Surgery*.

Of vesical suture, then, it may be said that, although it has not yet attained perfection, it is the thing to be sought; that it should always be tried in cases of rupture of the bladder, and at as early a date after the accident as possible; that its employment in the supra-pubic operation for stone, or for the removal of new growths, is still *sub judice*; bladder drainage being on trial in competition with it.

The two great dangers which have always confronted the surgeon in connection with epicystotomy have been the wounding of the peritoneum and infiltration of urine, giving rise to septic phlegmon.

By the three steps of progress already enumerated, — namely: (1) Antiseptics, (2) vesical suture or drainage, (3) rectal *ballonnement*, — these dangers are reduced to a minimum. To Petersen the credit of combining these steps belongs. He proposed the operation in 1880, and it has been adopted with considerable enthusiasm in various quarters. A description of the operation follows:—

The patient is washed, shaved about the pubes, anesthetized, every antiseptic precaution observed. A silver catheter is then introduced into the bladder, connected with which is a rubber tube carrying a cut off forceps. The penis should be encircled

by an elastic band. The bladder is now thoroughly washed out, and then injected with a four per cent. solution of boracic acid, or a weak solution of carbolic acid, or whatever antiseptic solution the operator may prefer, care being taken not to overdistend it. (Cheselden and Monod report cases of rupture from overdistension.) An injection of 200 grammes is necessary to secure sufficient elevation, and if no great resistance is experienced it is safe and desirable to inject as much as 600 grammes.

In hypertrophied, contracted, or irritable bladders, a less quantity must be used. After injecting the bladder a colpeurynter is introduced into the rectum, and from 400 to 600 grammes of tepid water are injected into it. This seems to be the chief agent in raising the bladder above the pubes. Incision in the median line, eight to ten centimetres, extending upward from the symphysis pubis and down to the aponeurosis, is now made; the aponeurosis is divided on a director. The interstice of the muscles is sought and opened; a yellow layer of fat then appears, which doubles over the cul-de-sac of the peritoneum, and which is covered by the fascia transversalis. This is seized at the lower angle by fine forceps and divided; in the opening thus made the finger is introduced and the peritoneal sac is pushed upward out of the way. Care should be taken not to tear away with the finger the retro-pubic cellular tissue in the vicinity of the vesical neck, otherwise a receptacle may be made to collect fluids and give rise to septic phlegmon.

The left index-finger, which has pushed up the peritoneal sac, is maintained in this position and serves as a guide to the bistoury, which now punctures the bladder in the median line.

The incision may be prolonged three or four centimetres, according to the amount of room desired. The incision into the bladder should be made cleanly and boldly. A venous plexus of considerable size is often divided, but will do no harm, hemorrhage ceasing with collapse of the bladder. There is probably no advantage to be gained by incising the bladder layer by layer.

The fluid now escapes from the bladder and the catheter is removed, and the stone or new growth, or whatever condition called for the operation, dealt with. The wound is then carefully washed with an antiseptic fluid, and the rectal colpeurynter withdrawn. In order to prevent the dropping down of the bladder behind the pubes, after its incision, some operators insert a small pair of double hooks, or a suture, previous to opening it. And this is an important step, as exploration of the interior and operations within the bladder are thereby rendered much easier. The bladder suture is now applied, as already described above; or drainage, as proposed by Perier, in its stead.

In the latter case two parallel drainage-tubes, open only at their vesical ends, are inserted into the bladder through the wound, sutured at the level of the

outer wound to its edge, and led out over the pubes into a urinal, the ends dipping into an antiseptic fluid. These tubes are led through the dressing, which is applied afterward, and are intended to act as siphons. The upper third of the outer wound is now sutured, and the antiseptic dressing applied. Some operators, in addition to the drainage-tubes just mentioned, insert a catheter into the bladder by the urethra as well. If drainage be employed, as just described, the wound and bladder should be washed out gently, daily, with a warm antiseptic solution through the tubes.

In spite of any contrivance, however, the urine will drain away in part over the edges of the wound, though the tubes carry away most of it. Hence the necessity of the subsequent washings and also of frequent change of dressings, even if antiseptic.

The drainage-tubes can be generally removed at the end of a week, and the wound closes in favorable cases in from fourteen to thirty days.

This is the modern operation and its modifications.

Even with its advances, the mortality with operators in general is as high as thirty per cent. But it must be remembered that, with but few exceptions, it has been reserved for cases in which other operations were considered impracticable; and some authors claim that the mortality for a similar set of cases by the lateral method is much higher.

Thus far in all hands the small mortality, and the manifold advantages of Bigelow's litholapaxy, put it at the head of all operations for the removal of such stones as do not require a cutting operation. It must, however, be noted that the supra-pubic operation when it has been undertaken by skilful operators, with the improved methods just detailed, has of late been attended by remarkable success, and bids fair to have a large future of usefulness. Volkmann, in the Congress of German Surgeons this year, has pronounced strongly in its favor, and Antal, of Buda-Pesth, reported in the same assembly four cases, in three of which he obtained first intention of the vesical and outer wound; the fourth case—in which first intention was not obtained—making also a good recovery. The operation is daily gaining adherents on both sides of the Atlantic.

#### ANATOMICAL NOMENCLATURE.

PROFESSOR WILDER has the courage of his opinions, and this is all the better as his opinions are of a kind that it requires some courage to maintain. He, as is well known, advocates a new anatomical nomenclature, which however simple it may appear to him, and to those who drew from him their first anatomical knowledge, is rather startling to the rest of the world. Our attention is called to this question, which is far from a new one, by Professor Wilder's list of names and synonyms for the use of those who attended his course of Cartwright Lectures in 1884, who must, indeed, have found it

indispensable. No one will deny that anatomical nomenclature is out of joint, but we are far from convinced that Professor Wilder was born to set it right. The day of fanciful resemblances has passed. Physiological function has some use in the case of certain muscles as in the superficial and deep flexors of the fingers, but it is no safe basis. In German the sternocleidomastoid is called the *kopfschäcker*,—the headnodder,—which rests on a mistaken notion of its action. If this uncertainty exist with muscles, how much more with regard to viscera? Chaussier wished to give names to muscles that would denote their origin and insertion, but the result was hardly encouraging.

Moreover, it is desirable to have a nomenclature that will identify analogous structures in different animals; but too much must not be expected in this direction, in view of the great uncertainty concerning the analogy.

The lectures to which we have referred, being on the brain, Professor Wilder's list of names and synonyms, which we now consider, refers only to parts of that organ. Most of them are not new to those who have paid attention to the subject, but some we believe salute the public for the first time.

Professor Wilder introduces *rima*, which means "the line formed by the rupture of the endyma along the lines of its reflection from entocortical surfaces." *Entocortium*, it is perhaps needless to say, means intra-ventricular. The five divisions of the brain based on development are respectively: PROEX, DEX, MESEX, EREX, and MEEX, and are honored with capital letters. The great transverse fissure is *rima*. *Adla* is the "mesal region of the procele," which, further interpreted, means the space just below the openings of the third ventricle (the diacelia) into the lateral ventricles (the procelia).

What is the advantage of the proposed system? We doubt very much if there be any that can counterbalance the evil of an additional nomenclature; for we hold as visionary the idea that it will ever be generally adopted. In these days of the downfall of the "Greek fetish" the jumble of Greek and Latin words seems peculiarly unfortunate. It is doubly surprising that it should flourish at Cornell, which, as far as we know, has never aspired to classical laurels. What we said above about the inconvenience of founding a nomenclature on function or on analogy applies equally to one founded on embryology. Science has not yet reached the point to justify it, and till then it is a house built on sand. Professor Wilder's nomenclature seems to us, however, to be utterly wanting in foundation. The system is partly embryological, partly morphological, partly topographical, partly, perhaps, functional, and the most definite idea that it suggests to us is of a growth from Greek and Latin roots, having fanciful branches and bearing an immense crop of words.

# THE THIRTY-FOURTH MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

This meeting will be held at Ann Arbor, Mich., from Wednesday morning, August 26, until Tuesday evening, September 1, 1885. The original intention of holding it at Bar Harbor was obliged to be relinquished, as it was found that suitable accommodations could not be secured at the latter place at the time proposed for the meeting.

The invitation to Ann Arbor has been supplemented by the work of a large and active local committee which has already sent out a preliminary circular, in which members of the Association are assured that there will be no lack of comfortable accommodations, and that the State University has granted the use of its buildings and grounds for the purposes of the meeting.

The headquarters of the Association will be at the University, and all the offices and meeting-rooms will be in close proximity in the several buildings of the University. Board and lodging for members and their families have been secured at moderate rates, and reduced return rates have been obtained from many of the railroads. It is proposed to run a special through train from Buffalo to Ann Arbor, leaving Buffalo on Tuesday morning and arriving at Ann Arbor the same evening. This will allow stopping for one or two hours at Niagara Falls, and will prove a pleasant excursion before the meeting.

Arrangements have already been made for a free excursion (on Saturday, August 29th) to the Saginaw Valley, by rail and steamboat, and numerous excursions on the lakes are planned, at reduced rates, to take place after the meeting. For further information in relation to the local arrangements members should address the local secretary, Prof. John W. Langley, at Ann Arbor.

For all matters pertaining to membership, papers, and business of the Association address the permanent secretary, F. W. Putnam, at Salem, Mass., up to August 20th. From August 20th to September 2d his address will be Ann Arbor, Mich.

## MEDICAL NOTES.

—Professor Grube has recorded in a Russian journal quoted by the *Lancet* a case of disarticulation at the hip-joint for a large sarcomatous growth of the femur which weighed about sixty pounds, or nearly a third of the total weight of the patient. Distinct cardiac mischief being present, it was deemed necessary to avoid the use of an anæsthetic, also that of Esnarch's bandage. The patient was convalescent in seven weeks.

A celebrated Parisian belle, says the *Popular Science News*, who had acquired the habit of whitewashing herself, so to speak, from the soles of her feet to the roots of her hair with chemically prepared

cosmetics, one day took a medicated bath; and, on emerging from it, she was horrified to find herself as black as an Ethiopian. The transformation was complete; not a vestige of the "supreme Caucasian race" was left. Her physician was sent for in alarm and haste. On his arrival he laughed immoderately, and said: "Madame, you are not ill; you are a chemical product. You are no longer a woman, but a *sulphide*. It is not now a question of medicinal treatment, but of simple chemical reaction. I shall subject you to a bath of sulphuric acid diluted with water. The acid will have the honor of combining with you; it will take up the sulphur, the metal will produce a *sulphate*, and we shall find a *precipitate* a very pretty woman." The good-natured physician went through with his reaction, and the belle was restored to her membership with the white race.

## NEW YORK.

—Health-officer Smith has issued a circular in regard to disinfection, in which he quotes the conclusions reached at the conference of representatives of the health departments of various seaboard cities, and of the New York State Board of Health, held at the Fifth Avenue Hotel, for the purpose of considering certain questions relating to quarantine. Having given the names of the gentlemen present, the circular goes on to say: "After careful deliberation the following conclusions were unanimously adopted: *First*, that the maximum period of incubation of Asiatic cholera may for quarantine purposes be assumed to be eight days, and that, in case of the disease occurring on vessels during the voyage hitherward, the quarantine observation of persons should extend to eight days from the last date of possible exposure. *Second*, that for fumigation of closed spaces, sulphurous acid gas may be commended, two or three pounds of sulphur being burned for each 1,000 cubic feet. *Third*, that for disinfection of luggage reliance may be placed on fresh chloride of lime, bichloride of mercury, or dry heat to 230° F., maintained for three hours, or boiling. *Fourth*, that in view of the danger of other contagion, as well as that of cholera, all rags imported to this country should be disinfected, either at the place of departure or on their arrival here. *Fifth*, that, if such disinfection be done abroad, it be required that either the rags be boiled for not less than thirty minutes and dried before baling, or treated with superheated steam for not less than eight minutes, and in such manner as to be heated to, or above, 230° F. in every part. *Sixth*, that inspectors should be appointed (by the department having control of the epidemic fund) to certify to the sufficiency of disinfection of rags according to the above rules, and that a consular indorsement be added to such certificate when disinfection is effected at the place of dispatch. *Seventh*, that, in absence of such certificate and consular indorsement, all rags be disinfected at the port of

entry. The above regulations will be the rules of this department until further notice.

“WILLIAM M. SMITH.

*Health-officer of the Port of New York.*

“P. S.—Rags disinfected by the sulphurous-acid gas, as per direction of Treasury Department circular, will be admitted when there is reason to believe such disinfection is faithfully and efficiently performed.”

Dr. Smith omits to include in the circular the following conclusion, which was suggested by Dr. Durgin, of Boston, and which was agreed to by the others present at the conference: “That, in the absence of such certificate and consular indorsement, all rags should be disinfected at the port of entry, except when accompanied by satisfactory evidence in writing that they have not been collected or haled in any district or place contiguous thereto, in which cholera, yellow fever, smallpox, typhus fever, scarlet fever, diphtheria, or the plague has prevailed during any part of the twelve months last preceding such collection.”

—The managers of Lodging-house No. 1, of the Sanitary Aid Society for the Tenth Ward, have submitted a report to the Board of Directors, showing that during April, when the house was first opened, they accommodated 600 lodgers. In May the lodgers numbered 1,579, and in June 1,771, making a total of 3,953 during the quarter just ended. All but 90 of this number were foreigners, and all came from the tenement-house districts of the Tenth Ward. The charge for a clean, comfortable bed and a warm bath is ten cents, and good meals are provided for three, five, and ten cents. The house has already become very popular among the class which it is designed to benefit, and it is gratifying to learn that it is now on a self-sustaining basis.

## Miscellany.

### BEFORE MEALS OR AFTER.

THE question whether a prescribed medicine should be taken before or after a meal is often put to the physician, remarks *The Therapeutic Gazette*, and occasionally requires some special consideration. The medicines which act as local irritants, such as the salts of copper, iron, zinc, and arsenic, in large doses are to be taken after a meal when the stomach is full, while small doses of medicines acting on the gastric terminations of the vagus ought to be taken before a meal. In some instances we have to consider chemical changes. Oxide and nitrate of silver, if intended to act locally on the gastric mucous membrane, must likewise be exhibited when the stomach is empty. It is not generally known, or at least observed, that iodine and its salts are to be administered on an empty stomach, as the presence of starch and acids, modifying or decomposing the preparations of iodine, would reduce or prevent their effect. The acids intended to affect the gastric juices are to be taken before a

meal in order to provoke an ample secretion of the gastric glands. If alkalis are to modify the gastric juices, they must be given during the meal; but if their absorption into the blood is desired, they ought to be ingested on an empty stomach, in order not to hinder the process of chymification by weakening the acids. [Bartholow has pointed out that acids before meals check undue acidity by preventing the osmosis of the constituents of the blood which form the acid gastric juice. Alkalies before meals in like manner increase the diffusion from the blood of its acid-forming constituents.] Metallic salts, especially corrosive sublimate, likewise tannic acid, alcohol, and other drugs, modify or destroy the digestive power of pepsine, and are hence to be exhibited solely before meals. Small quantities of alcohol, as contained in the ordinary and medicinal wines, do not injuriously affect pepsine like the liquors rich in alcohol. Iron, phosphates, cod-liver oil, and similar medicines may be taken during mealtime.

### THE TREATMENT OF OLD AGE.

DR. H. C. WOOD, in a clinical lecture on this subject (*Philadelphia Medical Reporter*, April, 1885), lays down three cardinal points to be observed in prolonging life in the aged: First, the protection from untoward influences, from exposure to which a large proportion of those die who are said to die of old age. An amount of exposure which may be nothing to a young man becomes a very serious matter to an old one; and one of the best protections from cold is a buckskin jacket. Every one who is seventy-five years of age, and whose physical powers are beginning to fail, should be put into a buckskin jacket extending from the shoulders to the hips. There is no flannel, silk, or anything else which will compare with buckskin in preventing chilling of the body. Chilling of the surface in an old person means a rush of blood to the internal organs, where from weakness of the vaso-motor system and the condition of the vessels contraction cannot take place, and the congestion is even apt to be followed by pneumonia or other inflammatory result. Such patients must be especially guarded against exposure to wind. Damp is feared by many and credited with causing many affections; but where damp has slain its thousands among the aged, high winds have slain their tens of thousands. This caution applies not only to old age, but to all cases in which there is a tendency to cardiac failure. High winds chill the surface, oppress respiration, and are exceedingly disastrous to the life of any person whose circulation is without power. I need not say anything in regard to preserving the nervous system from all shocks. Fortunately, as the intellectual powers become blunted, so do the emotional energies, and the old man is not so susceptible to emotional disturbances as is the man whose nervous system is unaffected by age. All accidents are, of course, to be carefully guarded against, and all excessive bodily and mental exercise. Remember, excessive is a relative term, and for the weak excessive may be very little. Rest is of great importance. Indeed, old people should spend many hours in bed. Second, the next point is in reference to diet. The

food should be light, but nutritious. Stimulating food should be withdrawn. Meat should be used but sparingly. What we start with to that we must come in this life. Man, who begins on milk, should in the last years of his life make milk the chief article of his diet. Finally, in regard to medicines. There are two drugs which are of the greatest importance to old persons. These are alcohol and opium. If your patient, approaching his eightieth year, can be made an opium-eater, you will in the majority of cases protract his life many months or years. In these cases the opium is to be used carefully, and in such a way that the patient cannot rapidly increase the dose. A number of years ago I was called to see an old man who was thought to be dying, but he is still alive at eighty-four. For the last ten years he has taken an opium suppository every night, but beginning with one grain, he has now only reached two and a half or three grains. Unless the patient has more than the ordinary will-power, it is essential that the opium be administered by some one else. Again, the use of alcohol in old age is of great importance. Every old person should take alcohol in some form three or four times a day. It should be given at meal-time. I think that it makes little difference whether dilute brandy, or whiskey, or some of the wines are selected; the wines are more palatable to some. It is also important to study the digestion of the patient, for in some it is found that the diluted liquors answer best, while in others the wines are most serviceable.

#### MIGRAINE AND ITS RELATION TO URÆMIA.

SOME light is cast upon this obscure disease by Mr. A. Drysdale, in *The Practitioner* for April, 1885. The cause of the disease is still left unexplained. Its hereditary nature is evident; it often affects several members and generations of the same family. It is sometimes related with phthisis, usually of the more chronic variety. Enforced chastity seems in some way to predispose to it, and it often disappears after marriage. Summer and hot weather certainly determine the periods of the attacks. Some suppose it to be due to want of sufficient sleep; others say that it is caused by excess of sleep, and especially by the habit of napping during the day. The author considers that the symptoms depend upon the accumulation in the blood of a peculiar poisonous substance, possibly allied to creatin and creatinin, and that this poison has a special affinity for the roots of the great nerves at the base of the brain, the optic, the ophthalmic, and the pneumogastric. The reason for supposing that this substance is allied to creatin and creatinin is the close resemblance of the symptoms to those of uræmia. The blindness, headache, vomiting, and subsequent stupor, bordering upon coma, in migraine are undistinguishable, except in degree, from the same symptoms in uræmia. The poison speedily produces its own elimination. The author then describes a severe attack, and states that, with regard to treatment, a drug must be administered which is known, from its physiological action, to be certain to reach the seat of the complaint. Caffeine, theine, and guarana fulfil these

conditions to a certain extent, but the best results are obtained from the use of nitroglycerin and sepiæ. The latter is especially successful in mitigating an attack, though it is not able to completely arrest one. Exercise, regularly pushed to the point of fatigue, is the only means of prevention. With reference to prognosis, the author states that, even when it is most intense, patients are not permanently injured by this malady; and that, when it occurs in conjunction with phthisis, the latter generally has a favorable issue.

### Correspondence.

#### THE IMPRISONED FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY.

*Mr. Editor.*—Will you permit a few final words upon "Imprisonment of the Fellows of the Massachusetts Medical Society"?

If my former communication seemed to show "scant courtesy" toward the Committee of Arrangements, it was unintentional. My criticism was not upon motive, but upon method.

The motive, however, appears to be revealed in Dr. Haven's letter in the *JOURNAL* of July 2d, which implied that some of the Fellows had shown, by their action at previous meetings, that they were deficient in good breeding, and that this meeting was deemed a fitting occasion to give them an object-lesson in manners.

Admitting that some of us who inhabit the outlying districts are open to this implication and need reproof, we are constrained to ask if some gentler method cannot be adopted in the future. The method chosen at the late meeting was an apt illustration of the old fable of "The Spider and the Fly."

When the crafty old spider, lying in wait, saw, in response to his invitation, the simple and confiding flies becoming entangled in his web, no doubt he enjoyed it hugely, but history informs us that the poor flies were not so cheerful.

When the unsuspecting Fellows were invited to "walk into my parlor," it was done with such an air of suavity and politeness that suspicion was disarmed. When, from their place of enforced detention, they saw the procession leaving the hall, and endeavored to join it in their proper places, "in order of their seniority," they were politely refused the privilege. When they protested against what appeared to them "scant courtesy," if not an indignity, they were told: "You cannot leave now, but you will be permitted to leave by another door later," which door was at the time fastened. When they then insisted upon their *right* to leave their prison and join the advancing column, they were politely informed: "You cannot get out unless you use violence."

And, finally, when the entrapped Fellows were on the point of asserting what they assumed to be their rights, and of making "a strike for freedom," a means of exit was happily secured through another channel, but whether or not by the grace of their captors, the writer is ignorant.

Although, doubtless, no allusion to the members of the Society who were thus so adroitly captured and confined, was intended, it would seem that some other course of procedure would be better in the future, as it is doubted that the gentlemen who were placed as sentinels over their compeers at the late meeting will consent to perform that humiliating service again. The writer would suggest, as an effective means of restraining the impatience of the hungry Fellows to reach the dining-hall, that the "bill of fare" for the dinner be printed and distributed to the members at the place of meeting. Probably a very brief study of

it would sensibly moderate their desire for an early seat at the dining-tables.

If some of the Fellows should still prove refractory and physical restraint still be deemed necessary, they would, no doubt, submit gracefully to the authority of policemen, who might use their billets in case of necessity. Or perhaps Mr. John L. Sullivan, the distinguished Boston "slugger," might render efficient service at the next meeting.

In point of dignity, this method would have a slight advantage over the one adopted at the last meeting. Seriously, this affair, which is now a matter of history,

was a *faux pas*, and only that, and its ludicrous side only will be remembered, for no one who knows Dr. Haven or his associates will suspect them of any intended discourtesy, and least of all does

ONE OF THE IMPRISONED.

[Membership of the Committee of Arrangements of this Society is very far from being a sinecure. The labor is fully proportioned to the honor involved. The arrangements, as a rule, are creditable to the Society and to the Committee. This fact, too, deserves more recognition than it always gets. — Ed.]

# REPORTED MORTALITY FOR THE WEEK ENDING JULY 4, 1885.

Deaths reported 2,967: under five years of age 1,495; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 922, consumption 338, lung diseases 227, diarrhoeal diseases 664, diphtheria and croup 93, measles 37, scarlet fever 31, typhoid fever 29, malarial fevers 23, cerebro-spinal meningitis 16, whooping-cough 11, puerperal fever 10, erysipelas eight. From scarlet fever, Brooklyn 11, New York and Philadelphia four each, Chicago three, Boston, District of Columbia, and Chelsea two each. From typhoid fever, Philadelphia 11, New York four, District of Columbia three, Chicago, Cincinnati, and New Orleans two each, Brooklyn, Boston, Lowell, Lawrence, and Waltham one each. From malarial fevers, Brooklyn and New Orleans six each, New York five, Chicago three and Baltimore two each, Nashville and Springfield one each. From cerebro-spinal meningitis, New York four, Chicago three, Philadelphia and District of Columbia two each, Boston, Cincinnati, New Haven, Haverhill, and Elizabeth one each. From whooping-cough, Brooklyn three, New York and Philadelphia two each, Chicago, Boston, Baltimore, and New Orleans one each. From puerperal fever, Chicago three, New York, Philadelphia, Brooklyn, Baltimore, Nashville, Charleston, and Springfield one each. From erysipelas, New York five, Philadelphia, Baltimore, and Cincinnati one each.

In 117 cities and towns of Massachusetts, with an estimated population of 1,451,534 (estimated population of the State 1,955,101), the total death-rate for the week was 13.48, against 15.00 and 16.56 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,306,416, for the week ending June 27th the death-rate was 17.6. Deaths reported 3,011: infants under one year of age 504; acute diseases of the respiratory organs (London) 184, measles 157, whooping-cough 106, diarrhoea 70, scarlet fever 36, fever 32, diphtheria 28, smallpox (London 13, Liverpool three, Manchester, Sheffield, and Sunderland one each) 19. The death-rates ranged from 12.0 in Hull to 30.6 in Manchester; Birmingham 16.5; Bradford 18.7; Bristol 12.3; Leeds 20.0; Leicester 15.7; Liverpool 21.3; London 16.3; Nottingham 12.6; Sheffield 20.5; Sunderland 18.5; in Edinburgh 15.4; Glasgow 21.4; Dublin 27.5.

For the week ending June 27th in the Swiss towns there were 26 deaths from consumption, lung diseases 20, diarrhoeal diseases 19, typhoid fever five, smallpox four, scarlet fever, erysipelas, and puerperal fever each two, diphtheria and croup one. The death-rates were at Geneva 16.2; Zurich 7.8; Basle 17.4; Berne 21.

The meteorological record for the week ending July 4th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, July 4, 1886.	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 4, 1885, TO JULY 10, 1885.

HAVERD, VALERY, captain and assistant surgeon. Assigned to duty at Fort Wadsworth, New York Harbor.

WYETH, M. C., first lieutenant and assistant surgeon. Assigned to duty at Fort Wayne, Mich. S. O. 149, Department of the East, July 2, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY, DURING THE WEEK ENDING JULY 11, 1885.

BYRNES, J. C., passed assistant surgeon. Detached from the Powhatan for duty at Navy Yard, Norfolk, Va.

CORDERO, F. J. R., assistant surgeon. To the Powhatan, as relief of Passed Assistant Surgeon Byrnes.

CRISIS, L. W., assistant surgeon. To Philadelphia, for examination preliminary to promotion.

BRENNAN, M. C., surgeon. Placed on waiting orders.

FILSIMMONS, P., surgeon. Duty on Receiving-ship Franklin, Norfolk Navy Yard, continued until July 1, 1885.

#### APPOINTMENTS.

BOSTON DISPENSARY.—At the July meeting of the Managers of the Boston Dispensary the appointments of medical officers were as follows: Dr. C. M. Green to be Obstetric Physician; Dr. G. A. Leland, Aural Surgeon; Dr. J. B. Swift, Physician to the Department for Diseases of Women; Dr. G. H. Monks, Surgeon to Central Office; Dr. R. A. Kingman, Physician to Central Office; Dr. W. D. Hodges, Surgeon to the Department for Diseases of the Rectum and Anus; Dr. H. W. Cushing, Dr. J. S. Howe, and Dr. W. F. Temple to be District Physicians.

#### BOOKS AND PAMPHLETS RECEIVED.

The Regiment to be adopted in cases of Gout. By Dr. Wilhelm Liebm, Professor of Clinical Medicine in Göttingen. Translated by John Scott, M.A., M.B. London: J. & A. Churchill, 1885.

A Treatise on the Science and Practice of Midwifery. By W. S. Playfair, M.D., F.R.C.P. Fourth American from the fifth English edition, with notes and additions by Robert P. Harris, M.D. Philadelphia: Lea Brothers & Co., 1885.

Palliative Measures in Ruptured Extra-uterine Pregnancy. By W. W. Jaggard, M.D., Adjunct Professor of Obstetrics, Chicago Medical College. (Reprint from Journal of the American Medical Association, December 13, 1884.) Chicago, 1884.

The College of Medicine of the University of Southern California. 1885. Los Angeles, Cal.

Asiatic Cholera. A Sketch of its History, Nature, and Preventive Management. By Oscar C. DeWolf, A.M., M.D., Commissioner of Health, Chicago, 1885.

An Accidental Division of a Pterygium leading to an Improperment in the Regular Operation. By A. E. Prince, M.D.,

Jacksonville, Ill. (Reprint from Archives of Ophthalmology, vol. xiv., No. 1, 1885.)

The Pulley Modification of his Limiting Tenotomy and Advancement of the Rectus Operation. With a report of a case of Section and one of Excision of the Rectus. By A. E. Prince, M.D., Jacksonville, Ill. (Reprint, New York Medical Record.)

Floating Minute Organic Matter in the Air and its Management to prevent Disease, and to mitigate or control it with a new Device for Atmospheric Purification, with an original illustration. By David Prince, M.D., of Jacksonville, Ill.

An Anomalous Human Lung, having Four Lobes on the Right Side. By William A. Edwards, M.D., Assistant Demonstrator of Clinical Medicine, University of Pennsylvania, etc.

Submucous Laryngeal Hemorrhage. By Ethelbert Carroll Morgan, A.B., M.D. (Reprint from Medical Record, March 21, 1885.)

The Forty-sixth Annual Report of the Superintendent of the Boston Lunatic Hospital to the Board of Directors of Public Institutions for the Year ending April 30, 1885.

History of the Clamp Suture of the late Dr. J. Marion Sims, and why it was abandoned by the Profession. By Nathan Bozeman, M.D. (Reprint from vol. ix., Gynecological Transactions, 1884.)

Surgical Notes from the Casbook of a General Practitioner. By William C. Wile, M.D., of Sandy Hook, Conn. (Reprint from New England Medical Monthly.)

Does quinine abort Pneumonia. By L. Emmett Holt, A.M., M.D., New York. (Reprint from New York Medical Record, February 21, 1885.)

Pneumonia in Young Children. By L. Emmett Holt, A.M., M.D. (Reprint from Medical Record, February 14, 1885.)

Medical Society of the State of Tennessee. Transactions, 1885. Fifty-second Annual Meeting. Nashville, Tenn., 1885.

Suena's Obliterators; their Construction and Uses. By Dr. Th. Weber, Helsingfors, Finland. (Reprint from Independent Practitioner, April, May, June, 1885.) New York Dental Journal Association, Buffalo, N. Y.

The Climate of Canada and its Relations to Life and Health. By William H. Hingston, M.D., D.C.L., L.R.C.S. Edin., etc. Montreal: Dawson Brothers, 1884.

Deviation of the Nasal Septum. By J. W. Gleitsman, M.D., Instructor in the New York Polyclinic, etc. (From the American Journal of the Medical Sciences, July, 1885.)

Atlanta Medical College, Atlanta, Ga. Annual Announcement. Session 1885-86.

Cholera: its Origin, History, Causation, Symptoms, Lesions, Prevention, and Treatment. By Alfred Sille, M.D., LL.D., Professor Emeritus of the Theory and Practice of Medicine, University of Pennsylvania. Philadelphia: Lea Brothers & Co., 1885.

Laryngeal Hemorrhage. By J. W. Gleitsman, M.D., Surgeon to the German Dispensary, etc., New York. (From the American Journal of the Medical Sciences, April 1885.)

Third Annual Announcement of the Medical Department of Niagara University, Buffalo, N. Y. Session of 1885-86.

The College of Medicine of the University of Southern California. 1885.

## Original Articles.

THE PATHOGENESIS OF CERTAIN AFFECTIONS OF THE SKIN.<sup>1</sup>

BY GEORGE H. TILDEN, M.D., OF BOSTON.

"Diseased nature oftentimes breaks forth in strange eruptions."

It is well known that the introduction of various drugs into the stomach is sometimes followed by the appearance of a cutaneous eruption, and that the connection between them is one of cause and effect. One of the most common of the so-called medicinal eruptions, consisting of the acneform, pustular, and sometimes furuncular lesions due to the administration of the iodide or bromide of potassium, has been attributed to direct irritation of the glands of the skin because of the attempted cutaneous elimination of the drug from the system, and the detection of iodine and bromine in the pus obtained from the cutaneous lesions gives to this idea apparent support. The histological character of such lesions, however, according to Duckworth, does not indicate that the cutaneous glands are primarily involved, while more recent microscopic investigation shows that although lesions caused by the internal use of iodine and bromine preparations may originate in dilatation and cellular infiltration of the capillary network which surrounds the sebaceous glands, the same process also affects bloodvessels which have nothing to do with the glandular apparatus of the skin, and may develop to such an extent that the consequent lesions represent a pustular dermatitis. The attribute of an eliminative pathogenesis, therefore, cannot be given to this variety of eruption until more evidence in its favor is forthcoming, although the occasional inception of the process in the neighborhood of the cutaneous glands is suggestive of the ancient maxim, *ubi irritatio, ibi affluens*.

Other forms of cutaneous lesions may also arise from the internal use of iodine and bromine compounds, and offer for consideration a large class of medicinal eruptions which differ in appearance from those just mentioned, and are independent of the physiological or therapeutic action of the drug to which they are due. They may be caused by many different drugs, and present a variety of forms, the most common and well recognized of which are as follows:—

(1) Simple and evanescent erythematous patches, unattended by constitutional disturbance, and not apt to be followed by desquamation, which have been observed after the use of quinine, antipyrine, copaiba, iodide and bromide of potassium, eucabs, and benzoate of soda.

(2) Papular erythematous lesions, attended with exudation into the cutaneous tissues, and resembling in some cases measles, in others the various forms of erythema multiforme, have been produced by the ingestion of quinine, antipyrine, copaiba, and iodide of potassium.

(3) A diffuse form of erythematous dermatitis, not unfrequently accompanied by constitutional derangement, generally followed by desquamation, and often closely simulating the rash of scarlet

fever, has occurred in consequence of the administration of salicylic acid, quinine, opium, morphia, and iodide of potassium.

(4) An urticarial eruption, consisting of wheals, is the most common of the medicinal eruptions, is apt to be combined with other forms and attended with constitutional disturbance, and has been described as following the use of copaiba, quinine, salicylic acid, antipyrine, iodide and bromide of potassium, opium, morphia, chloral hydrate, and arsenic.

(5) Purpuric eruptions, or circumscribed exudation of blood into the dermal tissues, sometimes accompanied by hæmorrhages from the mucous membranes, are reported as having occurred from the use of quinine, salicylic acid, iodide of potassium, and chloral hydrate.

Much less common than the above are:—

(1) Bullous or pemphigoid eruptions. Such cutaneous lesions occurring after the use of iodide of potassium are rare, but well recognized, and isolated instances of the same are recorded as taking place after the use of bromide of potassium and copaiba.

(2) Vesicular eruptions resembling eczema have been described as following the use of various drugs, but they are exceptional, and the details with regard to them are meagre.

Attacks of typical herpes zoster are described by Hutchinson and others as occurring during the administration of arsenic, but it is a question whether such eruptions are not to be regarded as coincidences rather than consequent phenomena.

(3) A scaly eruption, resembling psoriasis, is mentioned by Gower as appearing, in three cases, during the administration of borax.

The drugs which are most apt to excite cutaneous eruptions, when given internally, are quinine, salicylic acid, copaiba, preparations of iodine and bromine, and it is worthy of notice that the new remedy antipyrine is especially prone to give rise to cutaneous manifestations, being followed by them, according to one observer, in ten per cent. of the cases in which it is used. Contrary to the opinion of Besnier, who supposed them to be due to reflex nervous disturbance, caused by gastric irritation, these eruptions may ensue whether the drugs which excite them are introduced into the system by way of the stomach, by absorption through the mucous membrane of the rectum, by subcutaneous injection, or by contact with a wounded surface. They make their appearance shortly after absorption of the drug has taken place, are acute, and run a rapid course in comparison with the pustular dermatitis due to iodine and bromine; are not unfrequently ushered in by a chill and accompanied by vomiting, headache, and fever, offering a temporary but striking likeness to the acute exanthemata; are aggravated by the continuance or increase in the dose of the drug which causes them, and disappear upon its disuse. In some cases, however, the system seems to acquire a tolerance of the drug, and the cutaneous and other symptoms disappear, notwithstanding its continued administration.

The pathogenesis of the medicinal eruptions is of importance as throwing light upon other and analogous pathological processes, but its nature is too

<sup>1</sup> Read before the Massachusetts Medical Society, June 9, 1885, and recommended for publication by the Society.

complicated, and our knowledge too limited, to permit any such syllogistic and sweeping assertion of its neurotic character as has recently been made in the *Journal of Cutaneous and Venereal Diseases*.

With regard to the pustular lesions so often caused by the use of iodine and bromine compounds, the evidence, taken for what it is worth, indicates that the changes in the skin are due to direct irritation of its tissues, on account of the presence therein of iodine and bromine, two very irritating substances. The deposition of finely divided metallic silver in the corium, and consequent discoloration of the skin, which sometimes follows the long-continued administration of nitrate of silver, demonstrates the possibility of the accumulation of a drug in the cutaneous tissues after its internal use, while the typical inflammatory and suppurative character of the lesions in question suggests reaction to direct irritation, and the detection of iodine and bromine furnishes the material for such irritation. In most cases these inflammatory changes in the skin do not appear until the drug has been taken for some time, and personal idiosyncrasy does not seem to play so prominent a part in their causation as in that of the other varieties of medicinal eruptions, there not being manifest the same general condition of vascular irritability which is often connected with the latter. The production of the pustular dermatitis caused by iodine and bromine seems rather to be a question of the amount of the drug received into the system compared with the individual's capacity for its elimination by the proper channels: an interesting fact in this connection being the observation that in cases of Bright's disease, where the eliminating powers of the kidneys are crippled, this form of eruption takes place sooner and after smaller doses of the drug than usual.

As to the other varieties of medicinal eruptions, although they differ widely from each other in appearance, many of them are due to what looks like disturbance of the vaso-motor system, and belong to the so-called angio-neurotic lesions of the skin, the type of which is furnished by the wheal of urticaria; and both Pellizzari and Erb call particular attention to the general and increased irritability of the cutaneous vascular system which is present in these cases, a condition of things revealed by the ready formation of the so-called "taches cérébrales," first pointed out by Trousseau in connection with meningitis. Pathologically speaking, angio-neurotic lesions of the skin consist in various and varying degrees of dilatation of its capillaries, attended with more or less exudation of serum and wandering cells, separately or in combination, and such processes manifest themselves clinically by erythema of various types and urticarial eruptions. With regard to the bullous eruptions due to iodide of potassium, it may be stated that an angio-neurotic lesion of the skin, such as erythema or urticaria, may, by sudden and excessive exudation of serum, which causes the elevation of the epidermis *en masse*, develop into a bullous eruption, and it is a question as to how many of these pemphigoid lesions are of this nature. For the production of the hemorrhages into the cutaneous tissues which take place in the purpuric eruptions, there is apparently necessary some change in the capillary walls

themselves, for the red blood globule does not possess the power of amoeboid movement which enables the white blood cell to migrate through the protoplasm of which the walls of the capillaries are composed. This process is generally independent of any angio-neurotic manifestations, although it may be combined with them, and thus give rise to a hemorrhagic variety of such lesions. In what manner the presence of a drug, or some modification of the same, in the system causes such pathological changes in the skin: whether by disturbance of the central or peripheral nervous system, by irritation of the capillaries themselves, or by a combination of the two processes: is a matter of speculation which is premature in proportion to the extent of our ignorance, but the truistic assertion may be made, that the entrance in some way into the circulatory system of the drug which causes them is requisite for the production of these eruptions. In any individual instance the factor which seems to determine the morphology of the eruption is personal idiosyncrasy, or what Virchow has called the "mystery of individuality," the same drug generally causing the same form of eruption in the same individual, and it is an interesting fact that such idiosyncrasy may be hereditary.

The entrance into the circulation of vaccine matter and so-called septic material is also competent to excite pathological changes in the skin. In vaccination, besides the more common and localized eruptions of erythema, eczema, and erysipelas, which start from the point of inoculation and spread by continuity, there sometimes occur exanthemata, which, appearing after a certain period of incubation, upon regions of the body distant from the point of inoculation, often resemble in appearance angio-neurotic eruptions, and are apparently due to entrance into the circulation of vaccine matter, or possibly in some cases, as Behrend supposes, of the products of suppuration which has taken place at the point of inoculation. During the course of diphtheria and other septic processes, and notably puerperal fever, there not infrequently occur eruptions of the angio-neurotic type, being made up of erythematous and urticarial lesions, and probably the so-called puerperal scarlet fever and the "scarlet fever" after operations are of a septic nature, and not genuine scarlatina. Bullous, and very commonly purpuric, lesions may also ensue in consequence of septic infection, and several observers have expressed the opinion that all cutaneous lesions, occurring as a result of such infection, are metastatic in character; and although this may not be true of all, it is not unlikely that the petechial lesions are of this nature, namely, hemorrhagic infarcts of the skin caused by plugging of its capillary bloodvessels by emboli composed of microorganisms, more especially as some recent microscopic observations, by Watson Cheyne, of the lesions occurring in purpura hæmorrhagica seem to confirm this idea.

In the cases already considered the foreign material, or *materies morbi*, which excites cutaneous manifestations of its presence in the system, is introduced into the organism from the outside, and this may also be said of the acute and contagious exanthemata, of typhus and typhoid fever, of gland-

ders, of syphilis, of the oriental pest, and of infectious maladies, where cutaneous eruptions are exceptional and not characteristic of the disease, such as cholera, relapsing fever, and acute miliary tuberculosis; but instances are not wanting in which similar appearances may be caused by the formation in the organism itself of material which by its presence in the blood is competent to give rise to changes in the skin, and examples of this are furnished by scurvy, uræmic poisoning, and diabetes.

Chemical examination of scorbutic blood shows, besides other changes in its composition, increase in the amounts of water, fibrin, and albumen, and decrease in the quantity of its globular elements, and these changes, which are apparently caused by exposure to hardship combined with deprivation of certain articles of diet, notably fresh vegetables, are attended by the development of purpuric lesions in the skin and hæmorrhages into other tissues of the body. There is no reason for supposing scurvy to be an infectious malady, and the suggestion that the purpuric lesions of the disease may be due to the influence of the same microorganisms which are ordinarily harmless denizens of the mouth and other cavities of the body, but which in these cases are furnished with unusual opportunities for growth and development on account of the altered composition of the blood, is a curious instance of bacteriomania.

In chronic diminution or complete arrest of the renal functions, the consequent retention in the blood of waste products which should be eliminated by the kidneys usually manifests itself by headache, symptoms of gastric disturbance, and in severe cases by coma, but occasionally there are likewise produced cutaneous symptoms, consisting of a papular form of erythema, attended with exudation and followed by desquamation, which has been described under the name of erythema uræmicum. This form of eruption usually makes its first appearance upon the extremities, notably upon the extensor surfaces, and subsequently spreads to other parts of the body. Confluence of the original lesions sometimes causes the eruption to assume a likeness to that of scarlet fever, and in one case of unusual severity bullæ and purpuric lesions were formed in the skin, and hæmorrhages took place into the mucous membrane of the mouth.

The cutaneous manifestations which occur during the course of diabetes, apparently in consequence of the overproduction of sugar in the system, have been made the subject of a special article by Kaposi, and may be of the angio-neurotic type represented by roseola, erythema, and chronic urticarial lesions, or of a more frankly inflammatory nature, consisting of furunculosis, carbuncular lesions, and even gangrenous dermatitis. The presence of sugar has been demonstrated in these inflammatory lesions, which call to mind the similar cutaneous changes caused by iodine and bromine.

The eruptions which have thus far been mentioned are, properly speaking, not diseases of the skin, but changes in the skin, which are symptomatic of the presence in the circulation of some material which is foreign to the organism, and which either enters into it from without or is the result of perverted and incomplete performance of its physiological func-

tions. In an erude way they may be arranged in three groups, namely: those of an angio-neurotic nature, represented by the various forms of erythema and urticaria; those of a reactive inflammatory and suppurative type, consisting in acneform, furunculular, and carbuncular lesions, and those of a hæmorrhagic variety, manifested by purpuric eruptions, and it is worthy of notice that eczema, which is so common a disease of the skin, is so rarely met with in this connection.

The pathological changes in the skin, which are regarded as cutaneous diseases properly so called, are not unfrequently purely symptomatic in their nature, and a rational method of treatment does not lose sight of this fact, although the exact indications to be met are often obscure or entirely unknown.

The acute outburst of urticaria, sometimes accompanied by vomiting and febrile symptoms, which occurs after the use of certain articles of food in susceptible individuals, has its exact counterpart in the similar eruption following the use of various drugs, and many strange examples of such personal and gastronomic idiosyncrasy are recorded. The typical and self-limited course of erythema multiforme, erythema nodosum, and certain varieties of purpura; the prevalence of these diseases during the spring and autumn; the individual susceptibility which renders the patient liable to renewed attacks with the return of these seasons; the general feeling of languor and debility and arthritic pains which are often evident, and the occasional development of cardiac murmur during the course of these maladies, all go to show that their cutaneous lesions are merely symptomatic of some general and possibly infectious influence, the exact nature of which is entirely hypothetical.

The chronic varieties of erythema and urticaria, on the other hand, which by recurring attacks form such an unpleasant feature in the existence of the sufferers therefrom, are symptomatic of some disturbance of the various physiological functions of the body, and external applications have upon them but a temporary and palliative effect. They may often be associated with manifest symptoms of dyspepsia, with costiveness, and with improper modes of living, in which case the appropriate and generally effective remedy is to set right whatever is wrong, so far as lies in our power. The evil effects of the incomplete performance of the digestive and excretory functions are not limited to symptoms referred to various parts of the alimentary canal, and may even make themselves felt without any marked manifestations of the latter, and the lassitude, drowsiness, and general debility so often met with in these cases are probably but milder manifestations of changes in the blood which may even result in symptoms of coma, such as have recently been described as following, and probably caused by, dyspepsia. A sedentary life in a vitiated atmosphere, and improper food, are to many the ordinary conditions of existence, and plenty of fresh air, physical exercise, and regulation of the habits and diet are often more called for than drugs; but occasionally instances are met with where there is no obvious derangement of any but the cutaneous system, and where the functions of digestion and elim-

ination are performed with regularity and apparent completeness, and consequently our therapeutic efforts must sometimes be made at random. But the facts which come within the narrow limits of personal experience, that such cases are sometimes much relieved or even cured by the administration of salicylate of soda, atropia, or by a thorough-going course of purgative waters, are suggestive of future possibilities in the way of therapeutics, when our knowledge of the action of drugs and the indications for their employment is more exact than it is at present. There is no doubt also that eczema and other cutaneous disorders, which are not so purely symptomatic in their nature as those already mentioned, may be aggravated and kept up by similar conditions of the system, and a strict attention to the functional integrity and vigor of the body, in addition to local treatment, is often necessary to secure a successful result. Disturbance of the nervous system and exudative or inflammatory tissue changes are but the machinery of pathology, which is set in motion by what in the broadest sense of the word may be called irritation, and doubtless one form of such irritation is change in the composition of the blood by quantitative or qualitative modification of its various constituents, or by the introduction of foreign material, and the patient who makes the traditional demand for its purification may, in many cases, be nearer the source of his malady than the physician who is busy with the symptoms. However clumsy and ineffectual our therapeutic efforts may be, they should not be employed without a clear recognition of the close relations existing in matters of pathology between the body and its cutaneous envelope, which renders Dermatology, of all the special departments of medicine, the least independent of general pathological states of the system.

#### TEN CASES OF ABDOMINAL SECTION.

BY L. S. FOX, M.D., OF LOWELL, MASS.

THE surgical treatment for the removal of ovarian tumors and kindred diseases has reached that degree of success that ordinary cases seem to excite but little attention; but, as some of my cases present more than ordinary interest, and are my first series of ten unpublished ones, I offer no apology in presenting them to this Society.

It is proper for me to state, however, that my experience in laparotomy has not been confined to this handful of cases, but covers a space of twenty-three years as assistant to one of America's leading ovariologists, Dr. Gilman Kimball, together with having witnessed many such operations performed by the masters in this line—Sir Spencer Wells, Knowsley Thornton, and Lawson Tait. Therefore, if I venture an opinion, it will not be based upon a lack of experience and observation.

As regards the *modus operandi*, in a general way my experience has been that the minimum incision should be the rule in all cases of ovariectomy; one merely large enough to admit the hand is sufficient, unless the tumor is quite solid or firmly adherent.

Before tapping the cyst I have the patient turned upon her right side, and, while the fluid is running through the cannula, draw the sack forward into the

incision by a pair of vulsellum forceps. If a bulk of the tumor remain, — as frequently happens, if it be multilocular in type, — enlarge the opening into the sack, turn the edges out over the lips of the incision, pass in the hand and carefully break up the remaining cysts, after which, barring out firm adhesions, the sack can be readily extricated.

By using care in this step of the operation none of the cysts' contents can enter the peritoneal cavity.

The sack being extricated and the parts cleaned, the patient is then turned back in the usual position, and the pedicle secured. For this purpose I use a coarse, loosely braided silk, manufactured by Hepner, of New York, which has served me better than any other kind of ligature I have ever used. The ordinary hard-braided silk has so often got me into trouble by cutting the softer tissues and causing bleeding that I have ceased using it altogether.

The sack being cut away, the peritoneal edges of the stump are brought together and overcast with fine carbolized catgut, thereby covering the stump and open vessels by a layer of peritonæum. The abdominal cavity is now carefully sponged out, and all bleeding vessels secured. The wound is brought together in the ordinary way — by passing the needle through the entire thickness of the abdominal parietes, muscles excluded, taking each layer separately. The wound is now thoroughly cleansed, and covered with a strip of oiled silk, over which is a padding of Seabury and Johnson's antiseptic gauze. This is held in place by strips of adhesive plaster, enveloping the entire length of the dressing and passing two thirds around the body.

The silk used in these operations undergoes no preparatory treatment, except that of being boiled fifteen or twenty minutes. It is then put into a bowl of water and the instruments are kept in a tray of the same liquid. It is my purpose to have the water that is used at these operations previously boiled. As for the use of antiseptics, I believe in them only so far as is necessary to procure a strictly antiseptic condition of the room and its contents. For this purpose I use carbolic acid in spraying the room and mopping the floor. I also use it in preparing my instruments and sponges.

The clothing used about the patient is previously washed and carbolized and thoroughly dried. The patient's bowels are emptied the third day before the operation by a dose of castor oil.

The day previous to the operation she is bathed in weak carbolic water, and a vaginal douche of the same is given. On the morning of the operation the bowels are emptied by a warm-water enema. If there is any coldness of the hands or feet a dose of brandy is given before the patient is etherized. The temperature of the room should be comfortable, — neither too hot nor too cold — between 70° and 74° F.

I would like to suggest a slight modification of Keith's drainage-tube, which is simply a constriction, or neck, made just below the flange. It must not, however, be made at the expense of the glass, but must be of uniform thickness throughout. Its advantage — that of holding the tube in position — will be readily seen.

CASE I. This patient was thirty-four years of

age; single; had never suffered any inconvenience from the tumor; and was in good health at the time of the operation. It was a multilocular cyst, weighing eighteen pounds, and was removed from the left side. It was slightly adherent to upper left peritoneal surface. Patient made a good recovery.

CASE II. Multilocular cyst, weighing twenty-seven pounds, was removed from left side. There were no adhesions, pedicle stout and broad, and was tied in three sections. Patient made a rapid recovery, and returned to her home—forty miles away—in just four weeks from the day she entered the hospital. Pulse and temperature never above normal after the first day.

CASE III. This patient, sixty-five years of age, and always rather delicate, was operated upon at her own house, without any particular preparation of the room or herself. She was losing flesh and strength rapidly. Her nervous system was disturbed, and she was getting but little sleep. Both legs and feet were badly oedematous up to the knees. The tumor was multilocular, weighed thirty-five pounds, and was removed from the left side. The adhesions were firm and extensive. The sack, which was very tender, was ruptured several times in its removal, filling the abdominal cavity with its contents. The cavity was carefully sponged out, and the patient got well without any bad symptoms. No drainage-tube was used.

CASE IV. This patient, forty-three years of age, was always delicate. At the time I first saw her, although her trouble had been properly diagnosed by her attending physician, and she had been kept under a vigorous tonic treatment, yet she was extremely weak and emaciated. Her pulse was rapid, extremities moist and cold, and there was oedema of her feet and legs. Appetite and power of assimilating food were poor. Cystoma complicated with uterine fibroma was diagnosed and verified by the operation. There was no history of flooding; but for the preceding four months she had not menstruated. She had been tapped nine weeks prior to the operation, and eighteen pounds of fluid drawn off. The tumor was removed from the right side, was multilocular in type, and weighed twenty-seven pounds. There were adhesions to the upper left peritoneal surface and to the omentum. The pedicle, being short and very broad (five inches), was tied in three sections. The silk I was using at that time cut through in places and caused slight, but troublesome, bleeding. Patient made a good recovery. Temperature never above 99° after the first day. Heard from patient last week by her sending me another patient with the same trouble. She reported herself in good health, and has had no trouble since the operation.

CASE V. A multilocular cyst weighing twenty pounds was removed from the left side. There were extensive peritoneal and omental adhesions, and considerable oozing of blood followed their breaking up. Septic peritonitis set in on the fourth day, and for a week the patient seemed to be in great danger. Quinine and alcoholic stimulants, with opium, to relieve pain, were freely administered. The patient, after a lingering sickness, got well.

CASE VI. was a young Englishwoman, aged twenty-seven, mother of one child, who had never

enjoyed very firm health, and had always been subject to glandular swellings about the neck. At the time I first saw her the tumor would not have weighed more than five or eight pounds, but she had not then decided to have it removed.

The next visit she made me there were well-marked symptoms of pregnancy, and my advice was to postpone having anything done until the fourth month. I did not see her again until she was five months pregnant, when she came to the Lowell Hospital to have the tumor removed. On opening the abdomen only the lower border of the cyst could be seen, it being crowded upward by the impregnated uterus. It was a unilocular cyst of the left side, and weighed about fifteen pounds. The pedicle was very short and thick, which necessitated its being tied closely to the body of the uterus. Patient did nicely up to the fourth day, when she began to complain occasionally of sharp pains in the hypogastric region. Quite large doses of morphine did not control them, and at the beginning of the fifth day, without any apparently expulsive pains, she miscarried. The sex was well-defined, being that of a male child in the fifth month of development. There was a slight rise in the temperature following the miscarriage, also an increased fulness of the bowels. After rest and sleep the temperature fell to 99°, and remained so for three days. Then the lochial discharge increased and assumed an offensive odor, and she complained of chills, heat, and thirst. The left parotid, which was slightly enlarged at the time of the operation, increased to an enormous size, and was extremely painful. Leeches, poultices, and the external application of laudanum, gave her little or no relief. Deglutition was becoming very difficult. The temperature rose to 104° F. and the patient had every indication of being in a very critical condition. Let me here state that now, for the first time, I learned in talking with her husband that in her former childbirth she had puerperal fever and parotiditis. Following the advice of Dr. Thomas, I immediately washed out the uterine cavity with a two per cent. solution of carbolic acid at a temperature of 105° F. The fever abated, the parotid inflammation subsided, and all the unpleasant symptoms about the case disappeared within a week.

CASE IX. This patient, twenty-seven years of age, had always enjoyed the best of health; but for the past eight years had suffered the most agonizing pains through the pelvis, always distinctly referable to one or the other ovary, or both. The pain was described by her as lightning pain. At first these pains were associated with dysmenorrhœa, and for two weeks out of the four she would be incapacitated for work. For the last three years they have come on without special reference to her menses and were always accompanied by a variety of reflex symptoms, the most prominent and persistent of which was vomiting. For days at a time she would be unable to retain food on her stomach, and at times was unable to be nourished by the rectum from periodical attacks of diarrhœa. She was extremely wasted, pale, and nervous. Before I saw her she had received skilful treatment, but without benefit; and latterly her sufferings could not be even palliated,

unless by the use of anesthetics. Foreight months I treated her with the utmost persistence, using the best means at my command, including galvanism. Finally I advised the removal of the ovaries, and the patient gladly accepted my proposition, preferring death, even, to a life of pain and misery. A consultation was held with Drs. Kimball and Bass, who confirmed my opinion.

The operation was performed a little over two months ago, and thus far her suffering has been entirely relieved. The ovaries were non-adherent; not larger than normal, but were perfectly studded with small cysts, and contained about a tablespoonful of serum.

CASE X. This patient, forty-one years of age, mother of one child, — born sixteen years ago, — had enjoyed good health up to within two years, since which time she has had a history of menorrhagia; in fact, she was unwell a larger part of the time, and had grown quite pale and weak, so that she was unable to work.

I first saw her in consultation with Dr. Carolin, and diagnosed fibroma of the uterus and cystic tumor of the right ovary of the size of a large orange, but with a pedicle that would admit of its being easily pushed up under the ribs and down to Poupart's ligament. Operative interference was advised and accepted, it being my purpose to remove the cyst together with the left ovary. Making a small incision in the median line, the cyst was soon reached and removed; also a subperitoneal pedunculated fibroid, of the size of a goose-egg, from the posterior part of the uterus. This little growth had escaped observation, for it lay in a position that could not be reached, either externally or by rectal or vaginal touch.

The left ovary, which I was very anxious to remove, was so firmly held by the fibroid uterus against the bony pelvis that I could not extricate it without doing damage, and was obliged to leave it. The patient made a good recovery, and left the hospital in four weeks from the time of the operation.

#### THE RESULTS OF THE USE OF ANTIPYRINE AT THE BOSTON CITY HOSPITAL.

BY GEORGE R. SHATTUCK, M.D., VISITING PHYSICIAN.

IN October, 1883, with my colleague, Dr. F. W. Draper, I reported to this Society the effects of kairine as an antipyretic in typhoid fever, as shown by cases in which it was exhibited at the Boston City Hospital. In commenting on these cases I remarked "that the behavior of kairine as shown by them leads one to believe that a better antipyretic is possible, and that such will probably be ultimately arrived at, it may be by further experiments in the same direction which led to this discovery." Shortly after this was written, Professor Knorr, of Erlangen, and one of his assistants, succeeded in obtaining an alkaloid, a derivative of quinoline, of remarkable antipyretic properties, to which the name of antipyrine was given. Filehne, who introduced kairine to the profession in Germany, and who was a laboratory assistant of Professor Fischer, its dis-

coverer, made the first clinical experiments with antipyrine. This derivative of quinoline takes the form of a white crystalline powder, with but little taste, extremely soluble in water, especially in warm water; also soluble in wine. It is generally well borne by the stomach, even in large doses, and may be agreeably administered in wine or aromatics.

Kairine has already passed out of favor and out of use, as there were good reasons why it should; but antipyrine has met with a much greater and more uniform success. The different reports concerning its mode of operation and effects agree in all essential particulars; its antipyretic influence is fully as marked as that of kairine, whilst the administration is less frequent, and the fall in temperature is rarely accompanied by the chills and tendency to collapse, so often attendant upon the action of kairine. Its administration, even in full doses, is rarely attended by other inconveniences than profuse sweating and a slight vomiting without distress. Exceptional instances do occur in which the vomiting is prolonged and trying, and of course in such one loses more than one gains by giving the drug.

In a small proportion of the cases at the City Hospital here, and in a larger percentage of some of the German reports, the exhibition of antipyrine was followed by a somewhat variable eruption, which, however, commonly resembles that of measles — an eruption occasioning no inconvenience, and disappearing not infrequently during the continued use of the medicine.

Filehne's experience led him to recommend that antipyrine be given in three hourly doses of two grammes each; and it was in that way that it was at first generally given to get the full antipyretic effect. Latterly various doses have been tried. At the City Hospital we have given it according to Filehne's formula; we have also given only one full dose of two grammes, followed by two others of one gramme each, and we have tried single doses of one gramme. In some cases, after the effect of the three two-gramme doses had been attained, single repeated doses of five grains were given, with the aim of keeping down the temperature.

The charts which are shown, and which were prepared by the Senior Medical House-officer, Dr. W. L. Munro, show the results of these different methods. The charts are of patients in my own service and in those of other members of the staff. Most of the cases are of typhoid fever; but there is one of facial erysipelas, several of pneumonia, one of scarlet fever, one of sunstroke. In the last case two grammes were given subcutaneously at one time, and the patient made a rapid recovery, though brought to the hospital with a temperature of 107°.

Antipyrine was administered in several cases of intermittent, without interrupting the chills and without appreciable effect. This failure was anticipated from our previous experiences with kairine. A few instances are reported from Germany, in which the periodicity of the attacks was broken temporarily by large doses; but such instances are exceptional, and no antiperiodic action has been claimed or can be allowed. All these coal-tar derivatives resemble quinine in their antipyretic action, but differ from it in lacking the specific antiperiodic action upon malarial conditions.

Female. Typhoid Fever. Days of Month. Hours of the Day.

Female. Typhoid Fever. Days of Month. Hours of the Day.

Female. Typhoid Fever. Days of Month. Hours of the Day.

Female. Typhoid Fever. Days of Month. Hours of the Day.

Male. Stroke. Hours of the Day.

Female. Double Pneumonia. Three Thirty Grain Dose of Antipyrine on Three Successive Days.

Note. — A few selected charts showing the effect of different doses.

The fall in temperature ordinarily begins to decline itself in an hour after giving antipyrine, reaching its maximum in from three to five hours after the full dose of six grammes, divided in the German fashion, continuing on an average about eight hours, though sometimes lasting twice as long. A fall of from three to five degrees F. is very easily secured. The change in the pulse is by no means always proportioned to that in the temperature. The urine is somewhat diminished, free from albumen, and but little altered in color—in the last respect offering a contrast to urine after kairine.

We have had no experience with antipyrine in children. Two<sup>2</sup> of the German observers who used it largely in a children's clinic report that it is well borne by them, and suggest one decigramme for each year of age as a rule for the dose to be given.

Antipyrine has been in use at the Boston City Hospital since last June (1884), and was first suggested to me by Dr. F. H. Williams, who procured a small quantity and sent it to the hospital. An editorial notice of the drug will be found in the *Boston Medical and Surgical Journal* of August 14, 1884. For some months the supply was limited and had to be husbanded; at present it is in better supply, at \$1.25 the ounce, and may be had of Lutz & Movius, wholesale dealers, 37 Pearl Street, who import 200 ounces a week into New York to supply the country. The discoverer, I regret to say, put a patent upon the article, a proceeding which, however plentifully it may be prepared, will always be reflected in the price.

As a general result of our experience at the City Hospital, where further trials are still being made, I am able to endorse antipyrine as: (a) An efficient and reasonably safe antipyretic, without antiperiodic qualities.

(b) Whose exhibition in proper doses is, as a rule, unattended by serious discomforts or drawbacks.

(c) By reducing a high temperature it frequently substitutes calm for excitement and sleep for restlessness.

(d) Otherwise it does not usually modify the course of disease, and certainly not of typhoid fever.

(e) The quality of the sample used must be carefully watched in these synthetical compounds. A poor article will produce vomiting, chills, and collapse, when a good one will not; or, on the other hand, may be inefficient when the pure drug would have proved effective.

Antipyrine may be employed in a variety of febrile conditions, though its desirability in phthisis is questioned; but typhoid fever is the disease in which it is likely to be most largely and frequently used. When used in typhoid it should be distinctly without expectation of modifying the course of the disease. To emphasize our own experience on this point I may quote that of Alexander,<sup>3</sup> who reports a severe relapse in typhoid after the administration of fifty-four grammes of antipyrine in divided doses throughout the first attack; and of Dr. William H. Draper, in whose service at the New York Hospital,<sup>4</sup> of five patients dying from typhoid fever, one took ten grammes in ten doses during five days; a second

twenty-seven grammes in seven doses during six days; a third thirty-four grammes in twenty-one doses during eight days; a fourth forty-eight grammes in ten doses during seven days; a fifth three hundred and twenty-one grammes in sixty-five doses during thirty days.

It is extremely probable that we have only just begun to make the acquaintance of these synthetical laboratory compounds, and that, as kairine was a prelude to antipyrine, so the latter will be followed by something even better.

Thallin<sup>5</sup> is another quinoline product with which clinical tests have lately been made in Germany. Its antipyretic action is more like that of kairine than of antipyrine. The fall in temperature begins generally in from two to three hours after administration, and is usually accompanied by sweating. The rise is rarely postponed more than four or five hours, and often less, in which case it is apt to be attended by a chill. Neither vomiting, cyanosis, nor collapse have been remarked. The fall and rise of temperature are, however, less gradual than with antipyrine. The dose is from a quarter to three quarters of a gramme.

The laborer is undoubtedly worthy of his hire, and much special chemical knowledge and laboratory work is required for the evolution of these compounds; but one regrets that they should be covered by patents. This is not in accordance with a true scientific or professional spirit, or with what the past has led us to expect from Germany, and it is to be hoped in the future, if her physiological chemists furnish the profession with new means for alleviating human suffering, it will be, as in the past, without commercial restrictions.

## Hospital Practice and Clinical Memoranda.

### FLUID EXTRACT OF MANACA IN RHEUMATISM.

REPORT OF CASES TREATED AT THE BOSTON DISPENSARY SERVICE OF DR. G. M. GARLAND.

The following cases of rheumatism were treated with the fluid extract of manaca in the men's room of the Boston Dispensary during the winter of 1883. The extract employed was furnished gratuitously by Parke, Davis, and Company, with the request that its merits might be tested:—

CASE I. R. J. C., twenty-eight years of age, muscular rheumatism, acute attack. The left arm was much swollen from the wrist to the elbow, was tender, painful, and helpless. Patient also complained of his leg. Temperature 98.2° F. Ordered salicylate of soda.

Nov. 7th. No better. Stop salicylate of soda. Take fluid extract of manaca—fifteen drops every three hours.

Nov. 9th. Reports that leg is less lame, but arm is bad as ever. Increased the manaca to thirty drops four times daily.

Nov. 14th. Swelling of arm is nearly gone. Ankle is better, but patient still walks lame. Patient says he took salicylate of soda for one week

<sup>1</sup> Penzoldt and Sartorius, Berlin, Klin. Wochn., July 28, 1884.

<sup>2</sup> Fortschritte der Medicin, vol. II, p. 675, 1884.

<sup>5</sup> V. Jacksch, Wiener Med. Wochenschr., No. 48, 1884.

before applying to the Dispensary, but he perceived no benefit from it.

Nov. 16th. Doubled the dose to sixty drops four times daily.

Nov. 20th. Patient reports himself much better, but the arm is still somewhat swollen.

CASE II. P. G., sixty-four years of age; laborer.

Nov. 10th. Has had rheumatism for four months. Was all over him but now is confined to the left knee and instep. Ordered manaca, fifteen drops four times daily.

Nov. 17th. No improvement. Increased manaca to sixty drops.

Nov. 20th. Still no improvement. Stopped the manaca and gave him liquor potassii, which also failed to relieve him. Finally showed some improvement under the iodide of potash.

CASE III. P. M., thirty-two years old; laborer.

Nov. 15th. Has had rheumatism for three weeks. Confined to his bed with it for ten days. Is unable to work. Pain in both heels and insteps, which makes him lame. Also pain in shoulders. Finger-joints swell. Pulse 78. Temperature 99° F. Ordered manaca, thirty drops four times daily.

Nov. 17th. No improvement. Manaca, sixty drops four times daily.

Nov. 19th. Reports himself a great deal better. Ends of fingers still numb. Felt itch every evening. Would like to tear them to pieces. Never troubled so before. Continue manaca, sixty drops.

Nov. 25th. Reports no improvement. Instep and ankles very lame. Difficult for him to walk. Stopped manaca. Gave him liquor potassii, which he thought helped him more than the former.

CASE IV. J. R. K., fifty-nine years old; wheelwright.

Dec. 3d. Acute attack; one week standing. Began in the right arm. Abandoned that arm and went into the left arm yesterday. The left wrist is now swollen and red; the swelling extends some distance up the arm. There is great tenderness and continual pain. Patient could not dress himself this morning. Pulse 76. Temperature 98.5° F. Ordered manaca, thirty drops every three hours.

Dec. 6th. Reports considerable improvement. Pain and swelling have left the hand. Can move his fingers now.

CASE V. C. F. W., fifty-one years old.

Dec. 4th. Rheumatism began two months ago. Was in both arms, but is now limited to the left arm and hand. The hand is very much swollen. Cannot sleep at night on account of pain. Pulse 100. Temperature 98.5° F. Ordered manaca, thirty drops four times daily.

Dec. 5th. Has taken four doses of the medicine and feels better. The hand is less swollen and more movable. Dose increased to sixty drops.

Dec. 12th. Left arm almost entirely well. Right arm is now affected and is worse than the left one was. Pains him up to his shoulder. Renewed the manaca.

Dec. 26th. Reports himself about well.

CASE VI. J. D. D., fifty-one years old.

Dec. 10th. Has been troubled with rheumatism for four weeks. Grown worse during last week. Pain is situated across the sacro-pelvic articulation.

Patient has difficulty in standing or walking. Lies on the right side. Cannot lie upon his back. Never had rheumatism before. He aches when quiet and more so on moving. Pulse 80. Temperature 98.5° F. Ordered manaca, thirty drops four times daily.

Dec. 12th. Reports improvement. Can stand up straight now. Says the medicine makes him dizzy about half an hour after taking it.

CASE VII. M. M., sixty-five years old; fireman.

Dec. 12th. Never had rheumatism before. Yesterday was suddenly seized with pain in the right hip. Shot down into the calf of his leg and makes him very lame. Unable to work. Walks with a cane. Could not sleep last night on account of blisters. Appetite is poor and tongue is red. Pulse 74. Temperature 98.2° F. Ordered manaca, thirty drops four times daily.

Dec. 14th. Reports his hip improved, but the leg is still stiff. Limp on walking. Increase manaca to sixty drops.

Dec. 19th. No improvement. Changed to salicylate of soda.

Dec. 22d. Thinks the last medicine did him the most good.

Four cases of rheumatism were treated at the Carney Hospital with manaca. Two of the cases were old women over seventy years of age who had been complaining for a long time of rheumatic pains all over the body. No improvement in their condition was noticeable after the use of the manaca. The third case was a young woman of twenty-nine years, who had severe pains in her legs, from which the manaca gave her no relief. It was very doubtful if her pains were due to rheumatism, because there was a partial loss of motion in the legs. The fourth case was a man of twenty-nine years, who had suffered for six months with rheumatism. It affected his right knee at first. The pain and weakness attacked the right wrist until he was unable to work. He was discharged well after fourteen days' use of the manaca.

It will be noticed that all the above cases were non-febrile, as no case of rheumatic fever presented itself during the trial of the drug. Some of the cases, however, exhibited severe local symptoms and great personal suffering. Of course, very few deductions can be drawn from such a limited number of trials, but it is safe to infer that the fluid extract of manaca does help some cases of subacute rheumatism, and therefore deserves a place among other remedies recommended for that class of diseases. It would also seem that the drug must be used in large doses—from one half a drachm to a full drachm—in order to obtain satisfactory results. The remedy causes but little disturbance in the doses mentioned. Only one or two of the patients complained of feeling dizzy after using it.

— A correspondent writes that a woman, formerly a nurse, but now flourishing in the role of a "doctor," lately sent a written request for him to "bring a catheter and draw her patient's water." He found a catheter was large enough and more portable.

## Therapeutic Memoranda.

### ON THE INCOMPATIBILITY OF CHLORAL HYDRATE IN THE PRESENCE OF POTASSIUM BROMIDE AND ALCOHOL.<sup>1</sup>

BY GEORGE F. H. MARKOE,

*Professor of General and Pharmaceutical Chemistry in the Massachusetts College of Pharmacy.*

IN December, 1884, the writer had sent to him a bottle containing a mixture and a prescription, of which the following is an exact copy:—

R Bromid. Potass. . . . .	aa 5 iij.
Chloral Hydrat. . . . .	
Tr. Opil et Camph. . . . .	aa 5 iiss.
Syr. Zingiber. . . . .	

M.

Sig. One or two teaspoonfuls in half a wineglass of water every two to six hours. For sleep.

The claim was made by the physician that the pharmacist who dispensed the mixture had made a mistake, and the matter was put into the writer's hands for investigation. The mixture, as received, consisted of two layers, a clear dark-brown liquid, floating upon a light-colored dense liquid. The dark-colored supernatant liquid had an intensely strong taste in which the characteristic taste of chloral hydrate predominated, but it was modified by the presence of ginger, camphor, and anise, all of which could be recognized. On shaking the two liquids together a somewhat turbid mixture resulted; on standing, the two layers formed again.

The prescription was then made up, with the result that the ingredients separated into two layers, apparently in the same way with the mixture sent for examination. The writer could discover no practical difference in the two samples, and therefore concluded that some decomposition had taken place.

Anhydrous chloral (Trichlor-aldehyde  $C_2HCl_3O$ ) is a thin oily liquid, which will combine with an equivalent quantity of water to form Chloral Hydrate  $C_2HCl_3O, H_2O$ . Chloral also combines with an equivalent of alcohol to form chloral alcoholate  $C_2HCl_3O, C_2H_5O$ . Chloral alcoholate forms white needle-shaped crystals, is much less soluble in water than chloral hydrate, has a more disagreeable taste and is harsher in its action upon the system. When chloral hydrate was introduced into the practice of medicine, the writer was one of the first to make it in this country, and incidentally prepared and studied chloral alcoholate; two or three physician friends made trials of it, but found that, while it acted as a hypnotic, it was more disagreeable to the taste and harsh in its action, leaving unpleasant secondary effects. Knowing that chloral hydrate is changed into the alcoholate by solution in alcohol, it occurred to the writer that a similar decomposition had taken place in the mixture in question, the alcohol being furnished by the paregoric elixir called for in the prescription.

The following experiments were then made with a view to prove the supposition:—

(1) Potassium bromide . . . . .	60 grains
Chloral hydrate . . . . .	60 grains
Water . . . . .	6 fl. drachms
Syrup of ginger . . . . .	6 fl. drachms

<sup>1</sup>Read before the Massachusetts State Pharmaceutical Association, Pittsfield, Mass., June 1, 1885.

These articles formed a perfect solution which did not separate on standing.

(2) Potassium bromide . . . . .	60 grains
Chloral hydrate . . . . .	60 grains
Water . . . . .	3 fl. drachms
Alcohol . . . . .	3 fl. drachms
Syrup of ginger . . . . .	6 fl. drachms

In this experiment it will be noted that the ingredients differ from the original prescription only in the substitution of diluted alcohol for the paregoric. After standing a short time this mixture separated into two layers, the upper layer being of a light straw color.

(3) This experiment was with the same ingredients used in No. 2, except that the alcohol was not added until after the mixture had been standing for an hour. No separation took place before the addition of the three fluidrachms of alcohol, but the separation occurred promptly after the addition of the alcohol. These experiments prove that the alcohol is the cause of the trouble, and the writer thinks that the chloral hydrate is changed into the less soluble chloral alcoholate.

In addition to the experiments which have been described, numerous other ones were tried which served to confirm the results of those named. The writer found that the addition of potassium bromide, sodium bromide, sodium chloride, and magnesium sulphate to strong solutions of chloral hydrate, together with the presence of alcohol, determined a separation of the liquids into two layers. Ammonium chloride, ammonium bromide, potassium nitrate, and calcium bromide did not disturb the same chloral solutions.

The practical lesson to be learned from this incompatible prescription is that alcoholic preparations should not be prescribed with chloral hydrate, especially not in connection with the bromides of potassium and sodium, because if the solutions used are at all concentrated the chloral will separate as alcoholate, float on the surface, and a great risk will be incurred of giving a large overdose, the patient having received no caution with regard to the necessity of shaking the contents of the bottle before taking a dose.

## Reports of Societies.

### EIGHTEENTH ANNUAL SESSION OF THE AMERICAN OTOLOGICAL SOCIETY.

THE Eighteenth Annual Session of the American Otological Society was held at the Pequot House, New London, Connecticut, July 14, 1885.

The President, Dr. C. H. BRUNNEN, in the chair.

The Business Committee was announced as follows: Drs. C. J. Blake, Roosa, and E. W. Bartlett.

Dr. CHARLES J. KIPP, of Newark, exhibited the work of Gustav Retzius on the Anatomy of the Organ of Hearing of Vertebrate Animals.

The President reported the death of two members: Dr. John H. Dix, of Boston, August 25, 1884, and Dr. Edward T. Ely, of Colorado Springs, April 8, 1885.

The first paper was on

## INFLAMMATION OF THE ATTIC OF THE TYMPANUM,

by SAMUEL SEXTON, M.D., of New York.

After showing the greater importance of inflammation arising in the attic as compared with that arising in the atrium, the subject was introduced and discussed under two headings: acute and chronic inflammation of the attic. The latter had already been the object of considerable attention. It presents itself in the form of deep sinuses containing polypoid tissue, crusts, pultaceous matter, etc., leading from the inner end of the canal up into the attic into the antrum and sometimes through the membrana flaccida. These are often the result of acute inflammation in early life.

The atticus tympanicus is that portion of the tympanum lying above a plane extending transversely from the prominence on the inner wall, formed by the external semicircular and facial canals to the auditory plate on the outside. Beneath this plane lies the atrium tympanicum, over the attic arches the tegmen which also covers the antrum, the petro-mastoid canal, a varying number of cellules, and the Eustachian tube. The attic communicates freely with the antrum by means of the petro-mastoid canal of Sappey. The mastoid antrum lies behind and to the outer side of the attic in the spongy substance of the mastoid. It is usually larger than the attic and, as a rule, extends downward among the cellules of the mastoid process, giving off frequently a small passage, communicating with the cellules overlying the external auditory meatus. The attic is divided below into two compartments, the inner being the larger, by the incus and malleus, the cord ligaments, etc., which form a partial partition standing fore and aft. These compartments communicate freely with each other, overhead; with the atrium, below; the Eustachian tube in front, and with the antrum behind. The outer compartment is wedge-shaped, larger above and shut in below by the close approximation of the large ossicles to the auditory plate, except anteriorly and posteriorly, where two small openings allow drainage into the atrium below. The inner compartment also communicates with the atrium by an elliptical opening, surrounded on the inner side by the facial canal and on the outer by the large ossicles, the cord, ligaments, etc. All of these cavities are lined throughout with mucous membrane.

Acute inflammation of the attic may follow catarrh of the head, the exanthemata, the entrance of fluids propelled along the Eustachian tube, in bathing or from the use of the nasal douche. The very frequent occurrence of inflammation of the attic from these causes is readily accounted for when we remember that the Eustachian tube at its tympanic orifice opens by a free sweep into the attic as well as into the atrium. Irritating fluids seem always to be better borne in the lower than in the upper part of the tympanum. Inflammation of the attic may be simultaneous with, consecutive to, or independent of inflammation of the atrium. It is the more serious from the fact that swelling of the mucous membrane clogs the outlets and prevents drainage. In such cases, the membrana flaccida is red, the vascular turgescence extending above into the external auditory canal and sometimes downward about the short process of the mallet. Should

the disease progress further, the inflammation may extend beneath the margo tympanicus of the auditory plate, followed by effusion of serum and blood which presses away the membrana flaccida and integument of the canal, producing a bulging sac so great sometimes as to entirely conceal from view the membrana tympani, and may entirely fill the canal and present at the lumen as a purplish tumor. In some cases rupture of a bloodvessel of the tympanic plexus takes place, producing a sudden extravasation of blood. The outer tumor may not at first communicate with the attic.

Periostitis of surrounding parts may occur and extend along the surfaces of the canal, mastoid or squamous portions of the temporal bone. Inflammation may extend downward to the atrium; but as long as this does not happen, and the membrana tympani is unaffected, there may be little deafness, though autophonia may be present. In nearly all these cases inflammation in some degree extends into the antrum and mastoid cellules, or those overlying the external auditory canal, or in the tegmen. If the escape of secretions into the atrium or Eustachian tube is prevented, the case is more severe, and extension to the cranial cavity more to be feared. Inflammation of the antrum often persists after the tympanum has healed, drainage taking place through the Eustachian tube, or by a sinus through the cortex of the mastoid.

The subject of treatment resolves itself into a question of drainage and the employment of such constitutional remedies as tend to check the inflammation and prevent the formation of pus, as acetate, calx-sulphurata, etc. Owing to the impossibility of making an accurate differential diagnosis between the pains of pachymeningitis and neuralgic pains of otitis media, we should be very cautious about trephining the mastoid where pain is our only indication. It is manifestly useless to perform this operation after pachymeningitis has set in. Moreover, this question is one which in any given case must be left to the judgment of the attending surgeon.

## DISCUSSION.

Dr. B. ST. JOHN ROOSA, of New York, said: "I have nothing to say in regard to the anatomy of the tympanum; but the remedies mentioned, mercury and calcium-sulphide, are not in common use in the way recommended by the speaker. I have used mercury in the dose of one-tenth to one-fifth grain; and also sulphide of calcium without any favorable effect. I consider a warm room, a good nurse, taking care of bowels, and local measures as the most important measures. The internal treatment is of expectant nature. I should like Dr. Sexton to describe a case, indicating the manner in which he would use these remedies."

Dr. SEXTON: "The particular point of my paper was in regard to the inflammation of the attic, and not as regards the use of remedies. The remedies are given in small doses, but these are frequently repeated. In this way the effect is quickly obtained. The moment there are symptoms of purulence, I use the calcium-sulphide, and I think it controls the process. It has been used by Ringer and Otis in suppurative affections in other parts of the body. I have seen congestion and swelling over the mastoid disappear under the use of the calcium. When pus

collects in the mastoid region we should lose no time in operating."

Dr. J. A. ANDREWS, of New York: "I have here a drawing illustrating a case in which the inflammation was most intense in the upper part of the tympanic cavity, and a perforation was established between the mastoid antrum and external auditory canal. When I saw the case there was a great deal of swelling of the external auditory canal. Examination under ether showed a fluctuation in the superior posterior part of the canal, which I incised, and considerable blood and pus escaped. The patient made a good recovery. Two months later almost the entire canal was occluded with a membrane, which has since disappeared without operative treatment."

Dr. O. D. POMEROY: "Does Dr. Sexton believe that the administration of mercury in acute inflammation where there is pain relieves this pain, and if he does what is his theory of its action?"

Dr. SEXTON: "I have never used it exclusively to relieve pain, nor have I recommended it for that purpose. For the relief of pain I would recommend the use of aconite and pulsatilla, the latter especially, as there is no danger of a cumulative action with it. Four or five drops may be added to a wineglassful of water, and a sip taken every fifteen or twenty minutes. I am very sure that the sulphide of calcium given alone will relieve pain."

Dr. C. R. AGNEW: "When there is acute otitis media it is desirable to cut it short as soon as possible. It is important that we should know exactly what we want to do when we are called to such a case, just as we know what to do when called to any other emergency. If a patient came to me with the symptoms of beginning otitis media I should give him fifteen grains of calomel and order a Turkish bath, if that were accessible. With children there is always a certain amount of indefiniteness in the symptoms. I would ask Dr. Sexton what he would do in a case of acute otitis media catarrhalis in an infant six months old."

Dr. SEXTON: "In such a case I should examine the history, ascertain the general condition, ascertain whether it was subject to catarrhal trouble, ascertain the condition of dentition, ascertain whether there had been a previous attack of inflammation of the middle ear. If there were accumulation I should not hesitate to let it out. In the majority of cases where inflammation occurs at this age the membrane has already ruptured when the case comes under observation. If there were suppuration I should give calcium-sulphide. If there were simply catarrh I should give mercury."

Dr. CHARLES J. KIPP, of Newark: "I am surprised to hear nothing said of inflation of the middle ear. This relieves the pain. Where there is protrusion in front of the membrane incision gives relief to the suffering."

Dr. THORVALD, of Baltimore: "I have found the instillation of a warm solution of atropia of great service, a solution of the strength of four grains to the ounce. With this cathartics may be combined with great benefit. Another remedy which has been specially recommended by Dr. Allan Smith in inflammation of other parts of the body is the pyrophosphate of sodium in fifteen-grain doses

every two hours, keeping it up for four or five days. I have used it in inflammation of the middle ear with the threatened mastoid implication, and I am convinced that it is of real value. After perforation of the drum membrane I would recommend the use of boracic acid."

Dr. C. J. BLAKE, of Boston: "There is one anatomical point which has not been referred to by Dr. Sexton, and that is the reduplication of the mucous membrane in the upper portion of the tympanic cavity. This I have found in fifteen or twenty per cent. of two hundred specimens examined. These serve to separate the upper portion of the tympanic cavity from the lower. They become an important element in inflammation of this part, and may tend to retain secretions. Dr. Sexton has not referred to the acute congestions of the upper portion of the tympanic cavity. I have lately observed a series of cases of this condition in which there was a history of overstrain and nervous exhaustion. This condition suggests the acute pneumonias with precedent history of nerve exhaustion. In these cases free phlebotomy is the remedy. I would make an incision along the line of the posterior fold. This is followed by improvement in the symptoms."

Dr. SEXTON: "I would say, in conclusion, that I have used mercury and the sulphide of calcium for the last ten years in a large number of cases, and I am convinced that they are beneficial in a certain number of cases. If I had to give up anything I should rather give up the local applications than give up these internal remedies."

The next paper, on

#### THE TREATMENT OF CHRONIC OTITIS MEDIA,

was by W. W. SEELY, M.D., of Cincinnati.

He said that for quite a number of years the catheter almost supplanted all other interference. Then came the addition of medicated air and vapor and injection of various fluids, astringent, irritant, and alterative.

Of late years more attention has been concentrated on naso-pharyngeal affections as the starting-point and continuing-cause of this trouble. At this point attention was called to the possibility of treatment of ordinary pharyngeal troubles giving rise to ear complications. Every one knows the disastrous results following treatment of nasal catarrh. The great difficulty in these cases is to so treat the nose and throat as to benefit the tube and middle ear.

The speaker alluded to the abandonment of the nasal douche and the posterior nares syringe, and held that all applications to the naso-pharynx should be made with care, as all were liable to do harm. All of the points thus far were to justify the author's condemnation of the slurring of these cases by specialists in various ways, such as putting the catheter or balloon into the hands of the patient or parents, throwing over the treatment of the throat also to the patient. He claimed that this class of cases were almost all amenable to treatment, and only time and patience were necessary to manage them.

The speaker thought that the attention of the general profession was becoming too much centred on the Eustachian catheter as the only means of treatment, and especially as the only means of opening the

tubes. Often catheterization does harm rather than good, and some applications of boracic acid and vaseline, or what is still better, of the yellow oxide of mercury and vaseline through the nostrils, will open the tubes when the catheter has little or no effect. He said that salves had almost, if not quite, supplanted all other applications for nasal and naso-pharyngeal troubles.

The speaker concluded his remarks with the following:—

(1) That only experience of sufficient length of time (often lasting over months), in each case, can determine whether treatment shall be continuous (daily) or interrupted, that is, perhaps daily for a week, followed by an interruption of some weeks or months.

(2) Only experience in each case can inform us whether treatment is to be entirely directed to the middle ear, or entirely to the naso-pharynx, or combined against both.

(3) Only experience in each case can inform us whether injections into the *cavitas tympani* are called for. Under this head it was stated that direct medication either of the middle ear or naso-pharynx as routine treatment was unwise, till simple inflation had failed.

(4) Mechanical dilatation of the tubes is rarely necessary or advisable. Only in extremely dry states of the tube is dilatation followed by much success.

(5) Hearing-tests are not reliable, and hence patients with great deafness, great loss of bone conduction, etc., should not be sent away till the test by trial has been gone through with.

(6) Simple inflation failing, the greatest attention should be given to the naso-pharynx, even though it is in an apparently fair condition.

(7) Syringing, douching, and swabbing the naso-pharynx should be abandoned.

#### THE RELATIONS BETWEEN CHRONIC CATARRHAL OTITIS MEDIA AND CHRONIC RHINITIS.

By CHARLES H. BURNETT, M.D., of Philadelphia.

Dr. Burnett finds (1) a constant causal relation between chronic catarrh of the middle ear and chronic rhinitis and rhino-pharyngitis. The latter is chiefly of the hypertrophic form. The atrophic form, which is made to include the fibrous degenerations and the sclerotic forms as well as the truly atrophic, with shedding of epithelium and exposure of basement membrane, constitutes about fourteen and one-third per cent.

(2) The appearances of the *membrana tympani* in the first or numerous class are very diversified; so much so as to preclude a predication of the state of the middle ear and hearing from them alone. In the second class, however, the atrophic, the symptoms presented by the *membrana tympani* are more uniform and consistent, and the surgeon is able to predicate from them more precisely concerning the aural disease. Yet, on the whole, the appearances of the drum taken by themselves cannot aid greatly in the diagnosis of chronic aural catarrh. The faucial symptoms play a very subordinate part in diagnosis in chronic catarrh of the middle ear, because faucial and throat disease have little or no causal relationship to aural disease.

(3) *Tinnitus aurium* is more marked in the atro-

phic class than in the hypertrophic, as a rule. There is also a greater patency of the Eustachian tube in the atrophic forms of aural disease than in the hypertrophic, though it is found in both forms of naso-aural disease. It is most relieved by treatment of the nares and naso-pharynx.

(4) The treatment in the first class should be by cleansing and astringent sprays, with applications of preparations of iodine, never stronger than half-and-half. Nitrate of silver is not to be used at all in hypertrophic rhinitis. In the atrophic form the treatment must be cleansing, the removal of inspissations, if they occur, and then the application of stimulant sprays, preferably nitrate of silver, not stronger than four grains to the ounce of water.

Where the hypertrophies have become dense and large, requiring surgical removal, Dr. Burnett thinks the case should pass into the hands of the rhinologist.

A word of caution is given in regard to the use of the galvanocautery in the nares, since it, like the nasal douche, may lead to inflammation in the naso-pharynx and middle ear. The aural surgeon should always examine the nares, being prepared to treat the non-surgical forms of chronic rhinitis in order to properly cope with chronic aural catarrh.

#### DISCUSSION.

Dr. AGNEW, of New York: "It seems to me that there is an anatomical objection to the use of salves, and that is the impossibility of applying them to the whole of the diseased surface by means of Bowman's probe. I have used the nasal syringe for twenty years, and I am not prepared to accept the law that it should be abandoned.

"I am more willing to agree with the views of Dr. Burnett, but I think more stress should have been laid on the importance of hygiene, which is the most important element in the treatment."

Dr. ROOSA: "I think with the last speaker that the principal and only benefit to be obtained in the majority of these cases is from proper hygiene. I think that we do not need to continue our examinations very long or repeat them very often to determine whether or not we may expect to give the patient any relief. If I find diminished bone conduction, I think it unnecessary to go on and treat that patient."

Dr. E. WILLIAMS, of Cincinnati: "I have been in the habit of using the Eustachian catheter in every instance where I thought it indicated. Not only so, but I often introduce a flexible bougie through the catheter sometimes into the middle ear. In some cases of stricture of the tube this is quite useful."

Dr. KXER: "I have lately suffered with a catarrhal affection which at times causes me considerable annoyance. I have employed a salve of iodoform with vaseline with considerable advantage."

Dr. SELLY: "Since I have adopted the use of salves as a routine treatment, I have had more satisfaction than by any other treatment. They remain longer in contact with the affected part than do solutions, thus giving a more decided effect."

#### AFTERNOON SESSION.

Dr. SEARON presented a conversation-tube for the aural instruction of deaf-mutes. By means of this

tube the patient was able to hear his own voice and compare it with the voice of his teacher.

DR. GRAHAM BELL was then introduced, and called the attention of the Society to the greater number of children who were classed in institutions as deaf-mutes, but who, under proper treatment and education, could be made simply hard-hearing members of society.

He also referred to the importance of otologists formulating a list of causes of deafness to facilitate the proper registration in institutions for this class of individuals.

#### A CASE OF FATAL EAR DISEASE, BEGINNING AS A CIRCUMSCRIBED INFLAMMATION OF THE EXTERNAL AUDITORY CANAL.

By CHARLES J. KIPP, M.D., of Newark, New Jersey.

The patient, a married woman, aged twenty-eight years, was first seen nine months before her death. Since the previous confinement, which occurred four months before coming under observation, she had suffered occasionally with severe pain in and about the left ear. There was swelling and redness of the posterior upper wall of the external canal. There was no perforation and no otorrhea. Under the use of leeches, instillations of morphia, and inflation of the middle ear, there was decided improvement in the course of a month, when she passed from under observation.

Eight or nine months later the pain again appeared, shortly after a confinement. Examination showed furunculus of external meatus. This was soon relieved. There was no affection of the membrana tympani or middle ear. The patient continued to have headache, but there were no symptoms of mastoid disease. The patient continued to fail and finally died.

At the autopsy there was found evidence of intense inflammation over the entire extent of the arachnoid and pia mater. There was a collection of pus immediately over the posterior surface of the petrous portion of the temporal bone. Pus was also found on the pons varolii. A small abscess was found in the anterior part of the left lobe of the cerebellum near its junction with the pons. The mastoid cells were filled with pus. There was only a thin exudation in the middle ear.

#### DISCUSSION.

DR. BERNETT reported a case similar in many respects to that of Dr. Kipp, in which the patient died from what was diagnosed as cerebral abscess, but no autopsy could be obtained.

DR. E. E. HOLT, of Portland, Maine, reported the present condition of a patient from whom teratoid tumors were removed two years ago. The patient had remained free of the disease for one year, when they again appeared and have since progressed quite rapidly.

#### THE LOCAL USE OF COCAINE AND EUCALYPTI IN DISEASES OF THE EAR.

By DR. C. H. BERNETT, of Philadelphia.

Dr. Bennett had used both the sulphate and hydrochlorate of cocaine in painful affections of the ear to produce anaesthesia. He found neither efficient when the pain was due to inflammation in

dense tissues of the external auditory canal, as in furunculosis of this part, nor when acute inflammation occurs in chronically thickened periosteal and mucous tissues in the tympanic cavity. The hydrochlorate of cocaine, however, is efficient to induce local anaesthesia in four per cent. solution in cases of not excessive congestion of the skin of the fundus of the auditory canal and in the membrana flaccida of the drum membrane, as is observed in acute coryza, and attended with pain of a not continuous or intense variety. The solution may be applied to the inflamed tissues either by mopping it gently upon the affected portion, or by soaking a small dossil of lint and laying it upon the seat of inflammation, both procedures being done under perfect illumination of the fundus of the auditory canal by means of the forehead mirror. But solutions of cocaine are not competent to produce local anaesthesia in the external auditory canal profound enough to permit painless incision into it. The speaker had also employed eucalypti to produce anaesthesia in the ear; a five per cent. solution had been quite efficient.

#### DOES COCAINE HYDROCHLORATE, WHILE RELIEVING THE PAIN IN ACUTE OTITIS MEDIA, PROLONG THE CONGESTION?

By E. E. HOLT, of Portland, Me.

The speaker was satisfied that while cocaine relieves the pain and for the time holds the inflammation in check, yet after the effect of the remedy passes off the inflammation goes on unaffected.

DR. THEOBALD and DR. J. O. GREEN had found that in the nasal passages the drug exerted a similar effect; that although it at first relieved congestion, yet the congestion returned, and was even greater. Drs. Theobald and Green had come to the conclusion expressed by Dr. Holt.

#### ON THE DESIRABILITY OF ADOPTING A UNIFORM METHOD OF EXPRESSING THE RESULTS OF TESTING THE ACUTENESS OF HEARING.

By H. KNAPP, M.D., of New York.

After referring to the various methods which had been recommended, the following nomenclature was suggested, in which the plan pursued in recording the condition of vision is applied to the hearing:—

$H = \frac{24}{40}$ , normal audition for watch.

$V = \frac{2}{24}$ , normal hearing for whispering voice.

$V = \frac{6}{10}$ , normal for conversational speech.

$V = \frac{2}{6}$ , whisper or speech heard, but not understood; that is, qualitative perception of sound.

$V = 60' = 0$ , voice not heard at all.  $H = 0$ , complete deafness for all sounds.

$H = \frac{24}{10}$ , a watch of 24" hearing distance is heard in contact.

$H = \frac{P}{24}$ , a watch of 24" hearing distance is heard when pressed on ear.

$H = \frac{N}{24}$ , a watch of 24" hearing distance is heard when applied to mastoid.

$H = \frac{T}{24}$ , a watch of 24" hearing distance is heard when applied to temple.

$H = \frac{D}{24}$ , a watch of 24" hearing distance is heard when applied to teeth.

$H = \frac{F}{24}$ , a watch of 24" hearing distance is heard when applied to forehead (glabella).

$H = \frac{V}{24}$ , a watch of 24" hearing distance is heard when applied to vertex.

$H = \frac{v}{24u}$ , a watch of 24" hearing distance is heard everywhere (ubique).

To indicate that the watch is not heard at the places indicated the following are used:  $h_{24u}^c = 0$ ,  $h_{24u}^m = 0$ , etc., means that the watch is not heard in contact, over mastoid, etc.;  $h_{24u}^v = 0$ , means that bone conduction for the watch is lost.

A committee consisting of Drs. Knapp, Roosa, and Prout was appointed to consider the subject of a uniform method of expressing the results of examinations of the acuteness of hearing, and to report in 1886.

Dr. Knapp was appointed a committee of one to present the matter at the coming meeting of the German naturalists and physicians.

#### PREBYKOUSIS.

By B. ST. JOHN ROOSA.

The speaker applied this term to the failure of hearing which is incident to old age and which is not dependent upon inflammatory affections. It comes on after the age of forty or fifty years. Such persons hear badly in a noisy room. They hear the watch badly, but in a quiet room they can hear quite well. This is characteristic of this affection. In inflammatory troubles with the ear, the person often can hear pretty well in a noise, while in a quiet room he hears badly. These three symptoms go together: diminished bone conduction, hearing worse in a noise, and the disproportion between the ability to hear the voice and the watch.

Dr. E. E. HOLZ had examined a large number of persons with ear disease, who claimed that they could hear better in a noise than in quiet, but was unable to find that this was a correct observation. In noisy places the voice is raised and this might account for it.

Dr. ROOSA, in conclusion, said, in regard to the hearing better in a noise, he was convinced that patients with tympanic disease could hear better under such circumstances and cited examples.

Dr. SEXTON exhibited a glass ear syringe and an ear forceps with several attachments.

Dr. E. DYER, of Newport, Rhode Island, reported the case of a fistula of the helix greatly benefited by the application of the galvano-cantery.

The following papers were read by title: "A Case of Chronic Otitis Media Suppurativa, Resulting in Cerebellar Abscess, with the Autopsy," by O. D. POMEROY, of New York. "Otitis Media Suppurativa, Mastoid Disease, Pyæmia, Mastoid Operation, Recovery," by Dr. G. BACON, of New York.

The meeting then went into executive session. The following officers were elected: President, Dr. J. S. PROUT; Vice-president, Dr. S. S. SEXTON; Secretary and Treasurer, J. J. B. VERMYNE, of New Bedford, Mass.; Publication Committee: Drs. VERMYNE, BLAKE, and J. O. GREEN; Committee on Membership: Drs. CARMLIT, KIPP, and THEOBALD. Dr. F. L. CAPRON, of Providence, Rhode Island, was elected to membership.

The meeting then adjourned.

## SUFFOLK DISTRICT MEDICAL SOCIETY.

### SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND

#### HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MAY 13, 1885. The meeting was called to order at 8.20 o'clock, Dr. R. T. Edes presiding.

A summary of the records of the last meeting was given by the Secretary and approved.

Before the reading of the regular papers, Dr. J. W. ELLIOT presented a cancerous uterus, which he had removed by the vaginal operation on the previous day. The uterus was about twice as large as the normal uterus. The walls were much thickened and very firm. The mucous membrane was very thick and redundant, presenting the appearance of the so-called hyperplastic endometritis. There was no ulcerating cancerous surface on the specimen, the cancerous cervix having been torn off at the operation. Dr. Elliot called attention to the fact that it was impossible to define the limits of the disease without the microscope. The peritoneal surface was thickened, injected, and ragged. The uterus was found retroverted and bound down by tough peritoneal adhesions, which were with difficulty torn away at the operation. The uterine artery was enormously dilated, very tortuous, with an increased number of branches.

The patient was thirty-nine years old, and the mother of two children. About ten months ago she began to flow too much. This symptom continued to grow worse until she was much reduced. On December 29, 1884, she entered the Free Hospital for Women. On January 8th Dr. Baker removed the posterior lip of the cervix with a cancerous mass the size of half an orange. The patient was discharged from the hospital with the wound healed, except a few granulations. Two months after the operation she had gained twenty-eight pounds; but there was a slight return of the disease, which Dr. Elliot removed with the curette and scissors. Two months later the general health began to fail again, and the disease was found to have returned in the cervical canal.

On May 11th she returned to the hospital, and on May 12th Dr. Elliot removed the entire uterus through the vagina.

The operation was done by a new method described by Beckmann in *Archives für Gynäkologie*, 1884. I. Heft. By this method the parametrium is at first opened on both sides, then the bladder is dissected off from the uterus. The body of the uterus is then turned out through the anterior cul-de-sac. The broad ligaments are next ligatured, and the posterior vaginal wall is separated last of all.

The operation was very difficult on account of the adhesions which surrounded the uterus, and in tearing there was considerable hemorrhage.

In answer to questions by Dr. Putnam, Dr. Elliot said that the patient was thus far doing well.<sup>1</sup> The following is Dr. Whitney's report on the diseased part first removed: "Sections of tumor composed entirely of epithelial cells arranged in alveolar spaces by the presence of bands of connective

<sup>1</sup>The patient did well for four days. The temperature never rose above normal, on the fifth day she died. Examination of the wound showed some peritonitis and a quantity of blood in the pelvis. There had probably been a gradual oozing from the torn adhesions.

tive tissue. In places there is an arrangement simulating that of a gland, or as if the masses of cells had originated from such rather than from the epithelium of the free surface. The growth is evidently epithelioma."

DR. VINCENT Y. BOWDITCH read a paper describing Dr. Herbert F. Williams's

TREATMENT OF PULMONARY DISEASES BY MEANS  
OF "PNEUMATIC DIFFERENTIATION."

The paper reviewed the history of the various forms of medical treatment of disease by the attenuation of the atmosphere surrounding the patient, and gave an explanation of the physical and physiological phenomena upon which their efficacy depends, and then described the subjective and objective effects which were observed to follow the employment of Dr. Williams's appliance.<sup>2</sup>

DR. HENRY I. BOWDITCH said that for many years he had wished to get some apparatus whereby parts or the whole of a lung might be made to expand, for example, in certain cases of consolidation of the apices in early phthisis, so called, or larger portions compressed by pleuritic effusion, unresolved pneumonias, etc. When he read the pamphlet published by Dr. Williams it seemed to Dr. Bowditch that his wish had perhaps been attained. Accordingly, he had recently spent a week at Brooklyn, and, by the kindness of Dr. Williams, had seen some of his cases. Certainly most remarkable results had been obtained. One lady, the picture of robust health, had, according to her own account, and according to the report of Dr. Williams, had all the rational and strongly marked physical signs of phthisis. Dr. Bowditch could, on examination, find nothing but apparently perfect health, and no marked sounds in upper parts of the chest where marked signs were found before treatment in the cabinet. A youth who said he did his full day's work with other laborers at the navy yard had unmistakable signs of disease of the upper lobe before he began treatment. In one very singular case, where, according to Dr. Williams, there were signs of a large cavity in the right breast about the third rib, Dr. Bowditch found complete flatness on percussion from the clavicle to the third or fourth rib, and total absence of all vesicular or bronchial murmurs or r  le, even on coughing. Dr. Williams believed the cavity, and parts near, had been closed by cicatricial tissue. The appearances were certainly unique to Dr. Bowditch's experience. In the navy yard he found a slight crumple only upon strong effort made by the patient. The patient whom he observed under treatment expressed great comfort on coming out of the cabinet. One lady said she felt exhilarated, as if she had taken a glass of champagne. Dr. Bowditch tried the effect himself. The instant he made an inspiration the external air seemed to *rush* into every part of the chest and to distend the lungs throughout. For a moment he feared that he *would be unable to expire* and had to make strong contraction of all the respiratory muscles in order to breathe. In a short time he became accustomed to the unusual method of breathing. He observed that for several minutes after coming out he took, with great satisfaction and without the least difficulty, a series of

very deep but pleasant inspirations. Such, Dr. Williams said, was the usual effect on all patients.

In conclusion, Dr. Bowditch said that the instrument was a very powerful expander of the lungs. By it also medicated vapors could be thrown into the minutest air-cells, as had been amply proved by Dr. Williams by experiments on animals. It should be managed by intelligent persons. Dr. Williams frankly confessed that, while many cases had seemed to be cured or become stationary under it, he feared that possibly he had at times broken down old adhesions which it would have been well not to have severed, as judged from the subsequent course of the case. Only once or twice had he had these results. In consequence of the vast preponderance of unqualified good that had been accomplished, and notwithstanding the instrument was still on trial, Dr. Bowditch had determined to get one, so important did he deem it as an adjunct to our present method of treating pulmonic diseases. Dr. Bowditch was much impressed by the fair and honorable views expressed by Dr. Williams in reference to the whole matter. All he asks is that the profession should look at the apparatus and carefully watch its effects. He means, if possible, to prevent it from falling into the hands of ignorant pretenders to medical knowledge.

DR. F. I. KNIGHT said that there is now hardly a doubt of the benefit to be derived from the forced expansion of lung tissue. Striking proofs of the usefulness of this treatment may easily be produced from the records of many practitioners. This has been going on constantly since the introduction of the cabinet, in 1883, with striking results and mostly of excellent curative character. The physiological effects of the use of the cabinet are well presented in Dr. Bowditch's paper, and are often most desirable in pulmonary diseases. The cabinet is necessarily large, cumbersome, and expensive, and thus not adapted for general use, but doubtless the class of pulmonary specialists will largely employ the cabinet, as an important adjunct to other treatment. The advantages of the present instrument over the previous forms consists in the fact that the patient respires only the ordinary atmospheric air at a natural density, with or without the addition of medicament in the form of spray. In the earlier forms of the same instrument the air for *breathing* was frequently rendered more dense; or it was rarified, and thus probably prevented from exerting its highest degree of efficacy. This apparatus is certainly the best yet devised for this mode of treatment. Purely local treatment by Waldenberg's method may be practised when a cabinet is not at hand. If, by means of the cabinet, we are enabled to bring bichloride of mercury and other disinfectants into immediate contact with tubercle, we may certainly hope to influence thereby the course of this and other pulmonary disorders.

In reply to questions, Dr. V. Y. BOWDITCH stated that nothing specific was claimed for the iron as the substance from which the cabinet is made. Iron is used on account of its making an air-tight joint. The iron cabinet can be more thoroughly cleansed than can a wooden one. The mouthpiece is changed and replaced by a fresh one after each patient. All instruments and appliances are thoroughly cleansed and disinfected after each patient. It is

noticed that some forms of medication may be more comfortably employed in the cabinet than in the ordinary manner. Thus, iodine, which produces irritation and coughing when inhaled from the ordinary spray, can be inhaled in the cabinet without discomfort.

The increased ease of inhalation may be due in part to a more minute division of the medicines when given in the spray used with the cabinet. It is not known whether other drugs are rendered more easy of administration, as but few have thus far been made the subject of experiment. One theoretical disadvantage has been mentioned, which is that the forcible distension of the diseased pulmonary structures might allow the bacilli of tuberculosis to be carried into parts of the lungs not before affected by the strong and unaccustomed influx of an unusually large volume of air, and thus aid in the spread of the disease. This result has, however, thus far apparently not been demonstrated, and its frequent occurrence may well be considered doubtful.

The second paper was by Dr. GEO. B. SHATTUCK, entitled

THE RESULTS OF THE USE OF ANTIPYRINE AT THE BOSTON CITY HOSPITAL.<sup>3</sup>

Dr. C. P. PUTNAM asked if antipyrine can be kept indefinitely.

Dr. SHATTUCK stated that the substance is extremely soluble in water or wine, and can be kept in solid form or in solution for a long time. It is easily administered and is usually well borne by the stomach, causing, as a rule, neither nausea nor vomiting.

Dr. HAVEN thought that the qualities which antipyrine apparently possessed would make it especially valuable in infancy and childhood. One is in constant need of an efficient and safe antipyretic during these periods. A drug which will accomplish this and which can, moreover, be easily administered in small bulk, without irritation of the gastrointestinal canal, has many advantages. These conditions seem to be met by antipyrine, and, judging from published reports of its use in childhood, it is destined to become widely used and deservedly popular. The injurious effects of high temperature are much more marked in childhood than in adult life. The frequent occurrence of an irritative fever, producing, through the high temperature, symptoms and lesions of greater moment than the original condition or disease, make antipyretics almost essential in the treatment of sick children.

Dr. HAVEN reported the following cases in which the effect of antipyrine had been noted.

CASE I. Child aged ten years. Disease, pneumonia. Temperature 102°; 0.50 gramme of antipyrine given, which was followed by a fall of 2° in temperature in four and one-half hours, with no subsequent elevation until the evening of the next day, when the temperature was 101°; 0.25 gramme of antipyrine was now given, and in half an hour 0.50 gramme in addition, when the temperature again sunk rapidly and was not thereafter raised to an alarming degree.

CASE II. Child aged ten years. Temperature of 102°; 0.50 gramme of antipyrine was given when,

in less than two hours, the temperature fell to the remarkable extent of 4.8°. In six hours there was an increase of heat, and on the same evening the drug was again administered, with the result of reducing the temperature 2.1° in less than one hour. Subsequently in the history of this case there occurred a temperature of 105.2°, when, after the exhibition of one dose of antipyrine, the temperature fell 5.4° in less than two hours, with great relief to the distress and dyspnea. The child was perfectly comfortable for ten hours.

CASE III. Child aged twenty-two months. After a dose of 0.66 gramme of antipyrine a fall in temperature of 4.6° occurred, which has not been followed by a subsequent rise since that time (two days).

CASE IV. Child aged two months. Antipyrine was given in the dose of 0.10 gramme, and was followed by a reduction of body heat to the extent of *five and two-tenths degrees*. During a subsequent rise of temperature another dose of the same drug produced a fall of temperature of *five and eight-tenths degrees*.

Antipyrine seems to accomplish the reduction of body temperature by allowing an increased loss of heat from the dilatation of the cutaneous blood-vessels. As an antipyretic agent this drug must certainly be placed in the first rank, for we have only one other so effective means of securing a reduction of body heat at our command, namely, the cold bath. The drug seems to be equally applicable to all febrile conditions, which must recommend its use in exanthematic affections with high temperatures.

Dr. SHATTUCK added that it seems quite an easy thing to obtain a reduction of the body temperature to the extent of 4° to 6°. It is given equally well by the stomach or by hypodermic injection.

Dr. HAVEN stated that Dr. Mahomed employed antipyrine in a case in which the temperature was 100° F., and, after three doses of the medicine, the temperature fell *sixteen degrees*, and the patient made a rapid and complete recovery.

Dr. SHATTUCK observed that there is doubtless a variable degree of activity of the drug in different individuals, owing to personal idiosyncrasy, whereby usual doses may be followed by unexpectedly active results.

Dr. HAVEN thought that its effect is not so marked in pneumonia as in other febrile diseases, but was doubtless as great as that of any other antipyretic agent.

## Recent Literature.

*The Nature of Mind and Human Automatism.* By MORRIS PRINCE, M.D. Philadelphia: J. B. Lippincott Co. 1885.

If we divide the human race into Philosophers and Philistines, we may begin by saying that Dr. Prince's book is a very hard one to review; because, being a work on metaphysics by a metaphysical layman, there is danger, if we say nothing of its shortcomings, of ignoring the just demands of the Philosophers, and, if we attack it, of rejoicing the Philistines, who habitually desire to see the Philosophers at loggerheads, and all "higher speculations."

<sup>3</sup> See p. 74.

coming to grief. The person in whose honor the Philistines ought to erect a statue is the unknown genius who first made current the phrase of the moon being made of green cheese. If the worth of a formula be to relieve the mind that utters it, probably none ever did such service as this. What mode of dealing with a subtle or difficult inquiry can possibly compare for ease, completeness, and dispatch with the mode of classing it among speculations as to whether the moon be made of green cheese? And when we say that Dr. Prince's book is an inquiry into what kind of stuff real being is made of, and that he answers that it is made exclusively of mind-stuff, to whose lips among those of our Philistine readers does not the time-hallowed formula immediately recur? That reality is as little made of mind-stuff as of green cheese is the devout conviction of all Philistines, though if you ask what, then, it *is* made of, the only reply you get is: "Heaven save us from all such inquiries as that!"

Now we firmly believe that against the Philistine intolerance of speculation Dr. Prince's essay ought to be warmly defended and the importance of his hypothesis upheld. But we also believe that if he had given more time to the study of the philosophers who have preceded him he would have made a much better piece of work of it and carried it beyond the point at which it stops. The notion that the innermost reality of things is of psychic quality is no new one in philosophy. In modern times its career begins with Leibnitz's monads — not to count such writers as old Glisson the anatomist — and ends with men like Fechner, Zöllner, Renouvier, Clifford, Haeckel, Taine, Barratt, and others of less note. The merit of the theory is that it supposes no unknown and unverifiable form of being like "substance," or "matter," but presents us with something the *like* of which we already know by our own consciousnesses to exist; for it is a rule in hypothesis-making to assume nothing with which you are not, at least generically, familiar. But the difficulty with the theory is to represent it to the mind clearly, and to make concrete deductions from it of a positive and verifiable sort.

Now, as far as formulating his hypothesis goes, we think that Dr. Prince has left nothing to be desired. The first half of the book is really admirably written, and the clear discriminations of the author's own theory from representations of a vaguely similar sort throw the former into a high relief from which it ought never again to be suffered to lapse. We cannot but look upon this sharp accentuation of the theory as a point now for the first time permanently acquired to science.

Dr. Prince's theory is that the inner nature of matter is consciousness — not that consciousness and matter are two "aspects" of a transcendental reality, but that there is but one kind of reality in the world, which is consciousness pure and simple, and that material phenomena are only the result *in* one consciousness of influences exerted *upon* it by another. Verified in the case of brain matter, this theory is extended by analogy to all matter. In brain activity consciousness "is the actual physical change as it really occurs, not as it appears to us objectively. It may be called the essence of phys-

ical change in cerebral protoplasm. In other words, a mental state, and those physical changes which are known in the objective world as neural undulations, are one and the same thing; BUT THE FORMER IS THE ACTUALITY, THE LATTER A MODE BY WHICH IT IS PRESENTED TO THE CONSCIOUSNESS OF A SECOND PERSON, that is, to the non-possessor of it" (p. 55).

Nothing, as we said, can be more luminously brought home to the reader than this theory, and nothing is in its way better than Dr. Prince's exposure of the unintelligibilities involved in some other views of the relation of brain and mind. But it is somewhat a case of the beam and the mote, for to our thinking the unintelligibilities in Dr. Prince's own theory are not a whit smaller or fewer than those he finds elsewhere. It is easy, of course, to say that one consciousness can appear to another as a mass of cerebral matter, or as a stone. But how it can do so, or why it should do so, are riddles of the sphinx. If the consciousness that appeared bore any resemblance to the form under which it appeared, the strangeness would be alleviated. But Dr. Prince expressly shows (p. 81) that such likeness only occurs in exceptional cases, and in a generic way. If you are consciously thinking of your own brain, then the brain of yours which I think of does resemble its "reality," your consciousness, but in no other case. Even this case leads to paradoxes too subtle for expression here, but which may be found on page 160 of an article by Mr. Edmund Gurney in vol. vi. of *Mind*. But in the other cases the feeling of confusion one gets from trying to follow the processes out is perfectly bewildering, especially when one takes into view that states of consciousness not only must appear to each other as bits of matter, but *also* in their own proper shape, as when we enter into, and sympathize with, the mind of another. The purpose of a hypothesis is to give intellectual ease and abolish the sense of confusion. The postulate that all being is psychical banishes the notion that it may be foreign and unassimilable by our intellect, and is so far a welcome postulate. But when the panpsychism thus postulated is displayed under the form of a multiplicity of conscious agents (or patients) producing hallucinations in each other, whilst themselves intent on the entirely different hallucinations aroused in themselves, the intellectual relief begins to disappear in the effort to find *who's who* in this strange game of disguise and hide-and-seek. Dr. Prince propounds the hypothesis, but seems never to have thought of the jungle of difficulties it leads us into. The hypothesis should be but the starting-point of a long and tangled research. Dr. Prince propounds it rather as one who has said the last word on the subject. One may say that the entire drift of speculation nowadays is toward clearing up the hypothesis of panpsychism and redeeming it from the intolerable unintelligibilities that cluster over it at first sight. Many think this can be best done by giving up its atomistic and pluralistic form, and assuming an *anima mundi*, a total all-inclusive thought, as the one real reality, of which the finite consciousnesses are elements, like the words in a sentence. The only thing that is apparent in the midst of it all is what is apparent in Dr. Prince's book: that there is an immense intellectual pressure urging men who think in that

direction, and that the labors of any one of them may clear up particular points. For the unintelligibilities of panpsychism or idealism are all unintelligibilities of detail. Its *essential* assumption is of a thing with which we are at home. But the unintelligibilities of every philosophy that says reality is *non-mental* are unintelligibilities of essence. It is the fountain-head here which is forever an "unknowable," a thing foreign and alien and opaque to our rationalizing powers. Of course, the line of least intellectual resistance is through the difficulties of detail, and hence one cannot but believe an author to be guided by a sound instinct when he heads that way. On such premonitory instincts are great intellectual conquests often based.

The latter half of Dr. Prince's book has not the peculiar forcibleness and clearness of statement that distinguish the beginning. In the controversy between those who say consciousness is an inert accompaniment of brain action, and those who say it has a causal efficacy of its own, he sides with the latter. If consciousness is the reality, and the brain an appearance, the reality must be what does the work, if work there be to be done. But by what seems a rather arbitrary preference Dr. Prince, leaning on the law that all mental action is of the reflex type, and due to antecedent stimulation, says the work is done *passively, not actively* (p. 95), and so takes away from readers of a spiritualistic tinge of sentiment the comfort his words at first seemed to promise. These chapters on "Automatism" are, however, vigorous and incisive, and some very acute remarks are made in the discussion on Dr. Mesnet's case of the French sergeant, to which Professor Huxley gave such celebrity by his lecture "On Descartes's hypotheses that animals are automata."

Chapters on "Self-determination" and "Materialism"—less original than what precedes—end the book. If Dr. Prince will regard it as a beginning, and not an end, he may do good work in a direction in which, let the Philistines say what they will, work *must* be done, and in which any one may be proud of scoring his mark. Dr. Prince has scored his already by sharpening distinctions and clearing the fog, and by propounding certain solutions in a way so radical that once heard they are not to be forgotten.

#### ANOTHER INVESTIGATION OF THE DISCOVERY OF ANÆSTHESIA.

DURING the recent meeting of the Medical Association at New Orleans a paper was introduced by the delegates from South Carolina, requesting that the Association should investigate the facts relating to the discovery of the anæsthetic power of sulphuric ether. The subject was referred to the Medical Section, and was there again brought up for action by Dr. William Abram Love, who moved that a committee of three be appointed by the chairman to make the desired investigation and report at the next annual meeting. Accordingly Dr. Didama, the chairman, appointed the following committee: William Abram Love, Atlanta, Ga.; Henry J. Bigelow, Boston, Mass.; R. J. Dunglison, Philadelphia, Penn.

## Medical and Surgical Journal.

THURSDAY, JULY 23, 1885.

283 WASHINGTON STREET, BOSTON, MASS.

#### REPORT OF THE SURGEON-GENERAL OF THE NAVY FOR THE YEAR 1883.

HOWEVER merited may be the general criticism that has been passed of late years upon the efficiency of our navy, it is a source of just pride and gratification to the medical profession that the naval surgeons and the departments over which they are placed have so rarely fallen under any imputation against their ability or their honesty. We still are able to look with confidence to the army and the navy for the most accomplished and honorable of physicians.

The deliberateness of bureau methods doubtless explains the fact that the work of the year 1883, embodied in a report dated November 1, 1884, is first printed and distributed in the middle of the year 1885.

The ratio of mortality for the year was 4.55 per thousand of the force. This is a slight increase over the average mortality of previous years, the mean death-rate for the last fifteen years having been 4.40 per thousand. The total force afloat numbered 9,874. It seems, we must confess, somewhat surprising that these men, who might be expected to be of more than average physical health, should furnish upward of 8,500 cases of sickness during the year, the average duration of each being about eight days.

The vaccination record is of some interest, particularly with regard to the susceptibility to vaccination of those already having had the smallpox. In persons having good cicatrices about two fifths were revaccinated successfully, the remaining three fifths not taking. Where there was evidence of a former attack of smallpox 137 of the men were vaccinated without success, but 22 developed good vesicles.

From the incomplete returns for the year 1881 it appears that in the examination of 1,272 persons 52 are reported as rejected for color-blindness (4.08 per cent.).

The several naval hospitals at Chelsea, New York,

Philadelphia, Norfolk, Washington, and at Mare Island, California, are reported as being in need of further appropriations for repairs and to secure a greater number of employees to attend the sick. The inmates of the Government Hospital for the Insane at Washington were about sixty.

The Museum of Hygiene has received some important accessions since the last report, and facilities are now offered for the testing and the exhibition of various forms of sanitary apparatus. It also has an experimental laboratory, with apparatus requisite for work both in organic and inorganic chemistry, and for germ-culture. It has lately received Hemple's and Winkler's gas apparatus, with the spectroscope, polariscope, photometer, and other special instruments. The division for microscopy and photomicrographic work is also well supplied. The purchase of certain articles from the International Health Exhibition, London, has been ordered, including the apparatus designed by Mr. Francis Galton for anthropometrical examinations.

A quarantine station is required for the Maine coast, and Widow's Island, Penobscot Bay, some seventeen miles from the city of Rockland, is recommended as a suitable location for this purpose. It is fifteen acres in extent, and easily accessible from the sea, while furnishing safe anchorage. For building a wharf, digging a well, and erecting a small pavilion hospital, with offices, only \$5,000, it is estimated, will be required. A keeper will occupy the island when not in use for quarantine. On arrival of an infected vessel the keeper will be withdrawn, and the charge of the island and anchorage turned over to the commander of the vessel. Additional medical assistance and supplies can be furnished from Portsmouth in a few hours.

An important suggestion is made in reference to the post-graduate instruction of the naval surgeons, in special diseases of shipboard, those of various climates, and matters relating to the etiology and prevention of epidemic diseases. Attempts have several times been made to establish some form of school of instruction in connection with the medical department, but without much success. Post-graduate instruction is now furnished the naval officers at Annapolis, at the Torpedo Station, and at other places, and it is desirable that a similar work be done for the medical officers of the service. The Surgeon-general suggests, therefore, that as admirable instruction is afforded by the polyclinic courses at New York, Boston, and Philadelphia, the government purchase tickets for the principal subjects of the courses, — three months each, — to enable a certain number of the officers to attend the instruction during the winter and spring months.

#### THE THERAPEUTICAL USES OF RESOREIN.

By fusing galbanum and other resins with potash, acidifying the fused mass with sulphuric acid, and

shaking it with ether, there is obtained, after distillation, a soluble hydrocarbon belonging to the group of phenols, and called resorein. Its chemical formula is  $C_6H_4(OH)_2$ . It crystallizes in colorless prismatic crystals, or shining needles, fusible at  $110^{\circ}$  C., boiling at  $270^{\circ}$ , and is soluble in water, alcohol, and ether. Resorein has a bitterish-sweet savor and a feeble odor, somewhat like that of carbolic and benzoic acids, and its general properties very much resemble those of carbolic acid, a two per cent. solution arresting fermentation and decay. It coagulates and precipitates albumen; its crystals produce speedily though superficial cauterization. It is interesting to note that the synthesis of this substance has been effected by several continental chemists (Koener, Oppenheim, and Vogt). The known antiseptic properties of resorein early led to its employment in medicine, experimentation on animals having proved it to be safe of administration. Extensive trials were made in hospitals by Desnos, Dujardin-Beaumetz, Callias, Andeer, Sarbeck, Lielthelm, Bruger, and others. It is a decided antipyretic. It reduces temperature more quickly and to a greater extent than any other antithermic agent (Sarbeck). It renders the pulse slower and firmer, dilates the vessels of the face and skin generally, and causes great perspiration, almost like pilocarpine; the respiration is also slowed; these results are believed to be due to the reduction of the temperature. The action of resorein in lowering the temperature is exceedingly rapid and is very transitory, the pyrexia speedily returning. It is more apt to produce cerebral symptoms than quinine or salicylate of sodium; restlessness, delirium, rapid respiration, and even dyspnea and muscular twitchings are not unfrequently noted after administration in sufficient doses to produce antipyresis. On account of these inconveniences, and the short duration of the fever-fall obtained by it, this medicament is not now given for antipyretic effect.

Resorein was employed by Desnos in the treatment of typhoid fever, acute rheumatism, and phthisis. In typhoid fever its use was soon discontinued for reasons above given; in phthisis and rheumatism it was without effect.

It is in diseases of the alimentary canal that the utility of this drug has been most signal. Andeer has found it efficacious in chronic catarrh of the stomach with flatulence and frequent vomiting of mucous and food after meals. The stomach was washed out with a five per cent. solution. In intestinal affections with putrid decomposition and diarrhoea it was found beneficial. Dr. Asa F. Pattee, who read a paper on the "Therapeutic Considerations of Resorein," at the late meeting of the American Medical Association, has used this medicine extensively in various forms of gastric disturbances, as in eructations of gas due to food lying in the stomach and not acted upon by the gastric

juice, also in pain and vomiting from the same cause, in gastric dilatation, in ulcer of the stomach, in chronic catarrh of that organ, where "it breaks up the thick tenacious mass which coats the mucous membrane." He recommends using the siphon and washing out the stomach with a five per cent. solution, also the internal administration of resorcin, which may be given in doses of five grains an hour till six doses are taken. He asserts that he has found small doses of resorcin useful in chronic nasal catarrh and in the cough of chronic bronchitis, and recommends, especially in irritative spasmodic coughs, as whooping-cough, spraying the larynx with a fifty (?) per cent. solution. Dr. Pattee also speaks highly of the uses of resorcin as a gargle in sore throats (a one per cent. solution); and in diphtheria he would apply a fifty to seventy-five per cent. solution in glycerin to the diphtheritic membrane and surrounding parts, repeating it every hour, also at the same time giving internally from thirty to sixty grains during the twenty-four hours. Dr. Manino, in a recent article on resorcin in the *Zeitschrift f. Therapie*, reports favorably of the use of this medicament as a local application in epithelioma. He reports an interesting case of this kind which commenced as a small growth on the right cheek, about the size of a split pea, which caused a good deal of pain:—

"Continued scratching caused an abrasion of the skin, and on the slightest irritation it would bleed. Cauterization and excision only caused the growth to enlarge to a size of ten centimetres in diameter. The wound had a dark-red fungous appearance, with indurated edges, and gave off a profuse, thin, watery discharge. An ointment of resorcin and vaseline, 1—3, was applied twice a day for eight days, when a marked change for the better could be seen; a portion of the wound was beginning to heal over. After two weeks the ointment was weakened a little, and the case continued to progress rapidly. In a short time the whole surface was bridged over, and only a red scar remained. The treatment was painless and far more satisfactory than when caustics are used."

An ointment similar in strength to the above (one part resorcin to two or three of vaseline) has been used by Andeer as an application to simple or malignant carbuncle and phlegmonous erysipelas. "Resorcin," he says, "even when concentrated, causes no vesication or eruption, and is safer and more agreeable than any other of the aromatic disinfectants. Under the form of ointment it is the most absorbable of all, while never in the least toxic."

It would seem to be indicated as a topical agent in uterine catarrh and ulcers of the cervix uteri, and it is actually so employed and with success by many gynecologists. Prager speaks favorably of the uses of resorcin as a hypnotic, the medicine to be taken in half-drachm doses in sweetened water; it has

caused sleep in some cases where chloral had failed. He states that in all cases of paroxysmal colic, accompanying cancerous, dysenteric, tuberculous, and other diseases of the intestinal tract, and inability to sleep, resorcin exerts an important action, and the same is true of the intense pains of vesical and biliary calculi, which prevent sleep.

On the whole, it would seem that the profession has in resorcin a valuable remedial agent, worthy of further trial; one which especially as an antiseptic and disinfectant is free from many of the dangers and inconveniences which attend carbolic acid when too freely used.

#### THE TREATMENT OF HÆMORRHOIDS BY INJECTION.

UNDER the above title is an article by Dr. Charles B. Kelsey, of New York, in *The American Journal of Medical Sciences* for July. Dr. Kelsey is a strong advocate of the essentially modern method of the treatment of piles by injections of carbolic acid. The acid is of varying strength. He has three solutions constantly ready, one of fifteen, one of thirty-three, and one of fifty per cent. He sometimes uses the strong acid. In a severe case he would begin with the strongest solution; in a mild case, with one of the weaker solutions. He finds this method to be comparatively painless and uniformly successful.

The famous Western "pile cure" is composed of equal parts of strong carbolic acid and sweet oil, of which half a dozen drops are injected into each pile.

Dr. J. M. Matthews, of Louisville, gives the following rules: (1) Use the acid only in the smallest tumors. (2) Should it be used in a large tumor, inject once only in one portion, and wait several days, and then inject another portion. (3) Use the smallest amount possible in injecting, say one to three drops of the mixture of sweet oil and carbolic acid.

The injection turns the pile white, coagulates the blood in its vessels, and results in its shrinking away without the inflammation being severe enough at any one time to prevent the patient from attending to his business.<sup>1</sup>

#### Miscellany.

#### THE INTERNATIONAL MEDICAL CONGRESS AND THE MEDICAL PROFESSION IN BOSTON.

The following resolutions were adopted at a meeting of the physicians in Boston concerned in the organization of the Ninth International Medical Congress, and held in that city July 24:—

*Whereas*, we had been led to believe that the authority to organize and control the Ninth International Medical Congress had been permanently delegated by the American Medical Association to its original committee, thus providing against any radical changes in its published programme, and

*Whereas*, the American Medical Association has revised the action and annulled appointments of that

<sup>1</sup> Naphey's Surg. Therapeutics, seventh edition, p. 316.

committee in a way which we regard as detrimental to the interests of the medical profession of America and fatal to the success of the Congress;

Therefore, be it resolved that we, the undersigned, members of the medical profession in Boston and vicinity, concerned in the organization of the Ninth International Medical Congress, decline to hold any office in said Congress as now organized.

J. Orne Green.

S. C. White.

D. W. Cheever.

W. F. Whitney.

W. H. Baker.

E. F. Dunbar.

F. H. Gerrish, Portland, Me.

## Correspondence.

### SURGERY IN NORTH GERMANY.

[FROM AN OCCASIONAL CORRESPONDENT.]

HAMBURG, July, 1885.

Mr. Editor.—For those of us who for a while wish to free ourselves from our surgical traditions and to look at facts from the standpoint of well-trained and vigorous schools, nothing can be better than a trip to the surgical clinics in Northern Germany. We are so allied in communication with England that a visitor finds but little that is absolutely new to him in the London hospitals; Paris was the nurturing stepmother of most of our surgical teachers, and Vienna is the El Dorado now from which annually the rising generation of medical wanderers return with their portmanteaus filled with medical loot.

In Hamburg, Kiel, Berlin, Leipsic, Halle, one finds hospitals which a paternal government has found it for its interest to support, conducted by men whom an excellent system of drill and selection has made masters. At Hamburg, differing from the other mentioned places, one finds an old hospital, at present (though a new one is being built) of faulty construction and crowded with patients in ill-ventilated, untidy wards. The hospital has some 1,500 beds and a surgical service of 800; 100 under a continued service of one surgeon, Schede. It is at this hospital that the chief point of difference in the "point of attack" of the North German Surgical School and our own is most noticeable. With us soiled linen, dirty paint, unclean plastering, untidiness of the ward, sloppy and unmet floors are justly considered hygienic crimes. But we never think it obligatory for a surgeon to put on a freshly washed coat on every visit, or that one who operates with an old blood-bespattered coat may be hygienically a great sinner, and that one who operates without thoroughly scrubbing his hands with antiseptics until they are scientifically clean, may, in fact and not in fancy, be a death-dealing Azrael. It is not thought necessary for the dressers and the house students to wear every day, on their visits, freshly washed coats; they are often allowed to wear their own ordinary wooden clothes, even though the day before they may have been coughed upon by diphtheria and the sleeves may have been wet with the pus of a foul wound. The dresser, who may have just done up a sloughing compound fracture, assists at an ordinary operation without having scrubbed his hands, satisfied with a superficial dip in a solution of carbolic acid. The result is, that although our hospitals are models in appointments, ventilation, general cleanliness, and although we attempt antiseptic surgery, and take pains to isolate patients, yet we cannot claim to have banished erysipelas, or that form of cellular wound inflammation which prevents first intention,

makes compound fracture often an introduction to long suppuration, caries, necrosis, fistula, etc. At the above-mentioned North German clinics, what may be termed general dirt is not always well looked after, but the specific dirt, on the hands, instruments, sponges, dressings, etc., is avoided as carefully as in a biological laboratory where pure cultures are sought for, and the result is that in all of the above-mentioned places they claim to have banished erysipelas in all of the cases operated upon, the few cases of the disease being practically only those where erysipelas had been developed before the patients entered the hospital. This statement certainly corresponded with the temperature charts, the granulating wounds, the appearance of the patients as seen by the visitor. First intention appeared to be much more commonly gained than with us, and sinuses left after operations upon bone to be much more exceptional. And the following list of patients seen at the clinic on a morning's visit will be sufficient to prove that a rate of success is not due to the fact that the operations are not grave ones: ten cases of excision of the hip-joint, four being of adults, four laparotomies, three cases of trephining, two cases of excision of the knee, one case of removal of three fourths of the left iliac bone by a chisel, one case of removal of two thirds of the left parietal bone for caries and consequent cerebral abscess, one case of sawing through the patella, and dissection of the diseased synovial membrane, several cases of removal by a chisel of carious portions of bone in the epiphyses of the knee-joint, several primary amputations, one case of excision of the wrist, two cases of excision of the ankle.

These cases were all found to be in a very satisfactory convalescent condition, with the exception of one case of laparotomy, for malignant disease, where the patient showed signs of recurrence of the disease, though no fever was present; one case of excision of the hip, and one of the knee free from fever, but showing evidence of extension of the disease of the bone. A laparotomy for examination of disease of the gall-bladder was performed after the morning visit.

Varying in important matters, the detail of operations and dressings at the hospitals in North Germany may be described as follows: The surgeon washes his hands and arms in soap and water, then in a solution of corrosive sublimate (and in the graver cases in ether first to remove all fatty matter), using a nailbrush, which is kept in a solution of corrosive sublimate, and a knife to remove any foreign matter under the nails. The patient's skin is shaved and washed and scrubbed in the same way. An antiseptic spray is used in the room before the operation, but except in a few clinics, sepsis is prevented by irrigating the wound by solutions, weak antiseptic solutions, and by rigorous cleanliness of the instruments. These are kept in a tray under a carbolic solution, and as they are used and laid aside they are scrubbed by an attendant with a brush and again put in the tray. The assistants use the same precautions in cleanliness that the surgeons do, and all are dressed in freshly cleaned linen jackets and the operator and his immediate assistant wear india-rubber aprons, which are washed with corrosive. At the close of the operation the wound is well douched with a solution of corrosive (1-2,000 and 1-5,000) and the dressing applied. In general it may be said that iodoform is much less used in South Germany than with us, the dressings consisting chiefly of a few carefully folded layers of corrosive gauze, covered by layers of absorbent cotton prepared in sheets and covered so as not to pack in layers of corrosive gauze. At Hamburg and at Kiel, dressings are allowed to remain as applied immediately after the operation for two or three weeks (unless drainage-tubes are to be removed), and a large outer fold of peat prepared in gauze so as to resemble in size a large poultice, or dried moss (sphagnum) which is thoroughly absorbent; wood-wool is also used. Wounds treated in this

way appeared to do excellently, and the patients are spared the disturbance of frequent dressings. A change of dressings is done under the same precautions used in operations. Spray is used at the clinics of Bergmann and Thiersch, but at the latter clinic the care with which it is directed and looked after is not as great as is seen in London under Lister. In general it may be said that the German surgeon does not attempt to fight an enemy floating in the air, but is vigorous in putting an end to the opponent lurking in the unnoticed dirt on instruments, fingers, cloths, and sponges. Whether in long and large operations, where irrigation cannot be carefully carried out, spray as used in London may not be an additional safeguard, is a question which a traveler cannot be expected to answer. It is certain, however, that the results claimed by Schede can hardly be surpassed.

The improvement in hospital construction in the last ten or fifteen years in North Germany is very noticeable. The hospitals at Leipzig, Kiel, Berlin, and Halle are in many respects models, even looking at the matter from the standpoint of the best American hospitals. The same cannot be confidently said in regard to the nursing, which appears to be inferior to our training-school wards; at least as far as the impressions of a visitor can be trusted. Defective certainly is the custom, common in the university clinics, of allowing the students to crowd about the operating-table, thus interfering noticeably with the operator and transforming what should be a well-arranged, quiet, and orderly procedure into an arena crowded like a cockpit with a dispute as to the stakes—and in general it

is, of course, noticeable that the rights and feelings of patients are not regarded as considerably as is the aim with us. These mistakes we are not likely to make surrounded by the community American surgeons live in, but we certainly shall need to learn the perfection of drill in thorough asepticism the Germans excel in; a lesson which is by no means a difficult one, for an eye-witness can testify that after the students have once been drilled, the details of an operation or a dressing are conducted with as little friction and delay as could possibly be desired even by those who have been brought up to regard promptness and handiness an essential in the operating-theatre. It is to be hoped that, if any of the prominent continental surgeons, as they propose, visit us at the time of the coming International Congress, we in Boston may be able to show them our hospitals, not only models in nursing, in construction, and in neatness of surroundings, but also perfect in surgical cleanliness, and with a record which will show an absence of erysipelas, septicæmia, etc., in all operative cases.

As an example of Chauvinism, which the Germans are not free from, it was amusing for a Bostonian to be asked by a Berlin physician, and one who by his position as in charge of an enormous service must be a man of education and attainments, whether in Boston they aspired for *pleurisy*, as he considered it excellent treatment. On another occasion the question was put at Kiel, as the house-surgeon was showing with pride a newly built pavilion, whether the pavilion system of hospital construction had reached America yet.

## REPORTED MORTALITY FOR THE WEEK ENDING JULY 11, 1888.

Deaths reported 3,581: under five years of age —; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 1,038, consumption 344, lung diseases 176, diarrheal diseases 1,038, diphtheria and croup 192, typhoid fever 53, scarlet fever 47, measles 36, malarial fevers 31, whooping-cough 29, cerebro-spinal meningitis 16, erysipelas five, puerperal fever one. From scarlet fever, New York nine, Philadelphia eight, Brooklyn seven, Boston six, Chicago four, District of Columbia three, Cincinnati and New Orleans two each, Baltimore, Providence, New Haven, Lowell, Cambridge, and Lawrence one each. From measles, New York 11, New Haven 10, Philadelphia five, Chicago four, District of Columbia, two, New Orleans and Lawrence one each. From malarial fever, New York 12, New Orleans 11, Brooklyn and Baltimore three each, Charleston two. From whooping-cough, New York, 11, Philadelphia 7, New Orleans five, Brooklyn and New Haven two each, Baltimore and Cambridge one each. From cerebro-spinal meningitis, New York five, Chicago four, Philadelphia and Baltimore two each.

The meteorological record for the week ending July 11th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, July 11, 1885.	Barom- eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 12, 1885, TO JULY 17, 1885.

VOLLUM, E. P., lieutenant colonel and surgeon. To be relieved from duty in Department of the East on the expiration of his present leave of absence, and to report to commanding general Department of the Platte for assignment to duty as attending surgeon of the headquarters of that department. S. O. 159, A. G. O., July 11, 1885.

MIDDLETON, J. V. D., major and surgeon. Leave of absence extended fifteen days. S. O. 159, A. G. O., July 11, 1885.

BROWN, J. M., major and surgeon, CLARENCE EWEN, captain and assistant surgeon, A. W. TAYLOR, captain and assistant surgeon, and W. C. BORDEN, first lieutenant and assistant surgeon, ordered to prepare for field service. S. O. 61, Department of the Platte, July 9, 1885.

GRAY, W. W., captain and assistant surgeon. Relieved from duty at Fort Barrancas, Fla., and ordered for duty at Fort Columbus, New York harbor. S. O. 117, Department of the East, July 13, 1885.

POWELL, J. NICHOL, captain and assistant surgeon. Ordered from Department of the East to Department of the Missouri.

BIRMINGHAM, HENRY P., first lieutenant and assistant surgeon. Ordered from Department of the Missouri to Department of the East. S. O. 155, A. G. O., July 9, 1885.

EDGE, G. L., and BRYAN, C. S., first lieutenants and assistant surgeons. Ordered for duty with troops en route to Department of the Missouri. S. O. 78, Department of Texas, July 10, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED JULY 11, 1885.

FESSenden, C. S. D., surgeon. Leave of absence extended sixteen days on account of sickness. July 14 and 9, 1885.

BENNETT, P. H., assistant surgeon. Granted leave of absence for twenty-two days. July 9, 1885.

Cincinnati, New Orleans and New Haven one each. From erysipelas, New York two, Chicago, Brooklyn and Charleston one each. From puerperal fever, New York one.

In 108 cities and towns of Massachusetts, with an estimated population of 1,367,983 (estimated population of the State 1,955,104), the total death-rate for the week was 17.33 against 13.48 and 15.00 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending July 4th the death-rate was 18.0. Deaths reported 3,070; infants under one year of age 778; acute diseases of the respiratory organs (London) 192, measles 145, whooping-cough 128, diarrhoea 97, scarlet fever 29, fever 24, diphtheria 24, smallpox (London 26, Liverpool one) 27. The death-rates ranged from 12.8 in Birmingham to 27.6 in Halifax; Bradford 13.4; Birkenhead 16.8; Hull 15.4; Leeds 19.7; Leicester 14.6; Liverpool 21.1; London 17.3; Manchester 24.4; Sheffield 23.5; Sunderland 18.7. In Edinburgh 15.5; Glasgow 21.2; Dublin 29.6.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY, DURING THE WEEK ENDING JULY 18, 1885.

OWENS, THOMAS, assistant surgeon. Granted sick leave for one month. July 14, 1885.

#### APPOINTMENT.

Dr. Samuel A. Green has been appointed to the Massachusetts Board of Health, Lunacy, and Charity, to succeed Dr. H. P. Walcott, who was not reappointed by the Governor.

#### DEATH.

Died, in Springfield, Mass., July 15, 1885, Henry Robert Vaille, M.D., M.M.S.S., aged seventy-six years.

#### ERRATA.

TEN CASES OF PREGNANCY AND LABOR, COMPLICATED WITH FIBROIDS.<sup>1</sup>

BY JAMES R. CHADWICK, M.D., OF BOSTON.

## LABOR COMPLICATED WITH UTERINE FIBROIDS AND PLACENTA PRÆVIA.

CASE I.<sup>2</sup> May 12, 1875. Mrs. M., aged forty-two; had menstruated but twice in the past six months, the last time only two weeks before. Her abdomen had been slowly enlarging for six years, owing to a fibroid tumor; the growth had been more marked during the last few months. A large hard mass lay on the right side, rising nearly to the liver; a small very hard tumor formed a distinct protuberance just above the navel; the epigastric region was occupied by a solid body connected with the main tumor, but only reached on deep pressure. Per vaginam the cervix was felt to be soft, the roof of the vagina less yielding than usual; no distinct tumor could be felt. On May 17th, a more thorough examination disclosed flatness over the greater part of the left side of the abdomen, although nothing could be felt except some small nodules.

These, however, were not immediately in contact with the abdominal walls, but were only reached by deep pressure in the direction of the pelvic cavity. Fluid alone could interpose between the abdominal walls and the nodules, and produce flatness, yet at the same time be so readily displaced as not to be perceptible to the touch. Ascitic fluid was soon excluded from consideration by the immobility of the flat area on change of the patient's posture. A fibro-cyst seemed very unlikely from the relations of the tumors; pregnancy flashed into my mind as the only condition that would explain the phenomenon satisfactorily, and this suspicion the stethoscope confirmed by the discovery of the fetal heart-sounds two inches below the umbilicus. It is needless to add that the nodules in the left side were the feet.

The peculiar doughy resistance around the cervix, the impossibility of bringing any part of the child within reach of the fingers in the vagina, together with the history of a hæmorrhage within two weeks, caused me to suspect the presence of a placenta prævia as a further complication.

Mrs. M. passed to the full term of pregnancy without other untoward events than several smart hæmorrhages, requiring only repose in bed for their arrest.

On August 13th the uterus began to contract feebly, but with some regularity. Hæmorrhage set in, and soon assumed alarming proportions; it was checked by plugging the vagina with a Barnes's dilator.

Examination twenty-four hours subsequently revealed the fact that, despite the regular recurrence of the pains in the interim, the os barely admitted one finger. The pains had not increased in severity or assumed at all the force of true labor-pains;

yet the woman was beginning to show signs of exhaustion owing to them, and to the steady oozing of blood.

After consultation with Drs. A. D. Sinclair and E. G. Cutler, of Boston, ether was administered, and the cervix gradually dilated by digital pressure and manipulation. The placenta was prævia, but luckily only its border covered the os; this segment was readily peeled off and brought down into the cervix. The hæmorrhage was but slight, and soon ceased.

The placenta was now found to have its seat immediately over a large fibroid in the posterior uterine wall, that descended to the internal os, and proved a serious obstacle to the insertion of the hand. This was, however, at last effected, the feet seized and dragged down. The greatest traction that I dared apply only brought the knees to the vulva. With the exercise of great care, yet of considerable force, I insinuated a hand along the curve of the sacrum, between the abdomen of the child and the fibroid tumor; with great difficulty grasped one arm after the other, and brought them into the vagina, fracturing the right clavicle during the process. By continuous forcible traction the shoulders were finally delivered, though the head evidently remained above the brim of the pelvis.

Again and again I tugged upon the body while Dr. Sinclair pressed the head down from above the pubes. At length it descended suddenly into the pelvis and was at once delivered. The child, weighing ten pounds, lived.

The placenta not coming away and there being no expulsive efforts of the uterus, the former was removed, in a somewhat torn condition, by the hand. In order to make sure that no portion had been left, I introduced my hand into the vagina, and to my dismay felt it pass into the peritoneal cavity outside of the uterus. Above the fundus of the uterus could be felt the intestines, but they showed no tendency to descend into the pelvis. A careful examination of the rent by Dr. Sinclair and myself made evident that it was a transverse tear of the vagina, three or more inches in length, situated just below the insertion of the vagina into the posterior lip of the womb. Just above this lip, it must be remembered, was the large fibroid which had obstructed delivery.

Had I had my way at this point, I should have then and there extirpated that uterus by abdominal section, and the operation now known as Porro's would have been Chadwick's operation; but I was restrained by the counsels of Drs. Sinclair and Cutler, which I still recognize as wise from the standpoint of the experience of that day.

There seemed to be no hæmorrhage, so the ether was removed, the woman turned upon her back, and a tight bandage applied, by which means it was hoped that the edges of the wound would be kept in apposition, owing to the pressure of the uterus.

It is useless to give the subsequent history in detail. The first day was passed in perfect comfort; on the second, symptoms of peritonitis began to appear. On the third day the abdominal distention was so great as to require puncture of the intestines to allow the escape of flatus. Through the same trocar I essayed the injection of nutrient

<sup>1</sup>Read before the Massachusetts Medical Society, June 9, 1885, and recommended for publication by the Society.

<sup>2</sup>The reports of this and the next case are condensed from the *Trans. Am. Gynec. Soc.*, vol. II. pp. 255-267, 1877.

and stimulant fluids into the intestinal canal. The feasibility and objects of this procedure were fully set forth in a paper which I read before the New York Obstetrical Society on November 2, 1875.<sup>3</sup> On the fourth day septicaemia and delirium set in, terminating fatally on the fifth day.

No autopsy could be obtained.

Several points in this case seem to merit consideration.

I will not dwell upon the very misleading character of the history as elucidated at the first visit, but I wish to emphasize the importance of having perfect accordance between the signs obtained by the different methods of examination,—in this instance, by palpation and percussion. By a neglect to recognize the discrepancy between the testimony derived from these two sources, I failed to make a correct diagnosis at my first examination, though I repaired the omission at the second visit. This point is further illustrated by

#### PREGNANCY COMPLICATED WITH ONE FIBROID TUMOR.

CASE II. 1876. Mrs. F. M., thirty-three years of age; had been married fifteen years without having had children or miscarriages. Menstruation had always been regular until seven months previously; since then it had not been seen.

Five months before, she had consulted one of the most eminent and trustworthy physicians of Boston, whose notes describe the cervix as "hard, red, and granular," almost exciting a fear of commencing cancer. Nothing else abnormal was recognized.

Three months later he records another examination as follows: "Cervix soft, os patulous; several large distinct tumors in the abdomen, forming a mass four or five inches in diameter, and lying between the umbilicus and pubes; one tumor was more prominent than the others. Other indistinct tumors in right iliac region. *Dulness on percussion extends beyond the distinct tumors.*" An unfavorable prognosis was given, which was concurred in a month later by one of our most prominent ovariotomists. She had not been examined since that time until, chancing to be making a professional visit in Holbrook, Massachusetts, I was requested to see her in consultation with Dr. Kingsbury, of that town. It required no great acumen on our part to recognize, at that advanced stage, the existence of pregnancy at about the end of the seventh month, complicated by a fibroid tumor larger than a man's fist, in the anterior uterine wall.

The patient was delivered safely by Dr. Kingsbury two months after; at the end of another two months I was unable to find any trace of the fibroid.

I believe that the suggestion conveyed in the phrase which I have italicized would, if followed up, have given a clue to the true condition, although it was too early to hope for decisive signs at that time.

Another diagnostic point of the utmost significance is the sudden, rapid increase in size of a fibroid tumor which has been stationary for some time, especially if this coincides with absence of menstruation. This was the chief factor in the diagnosis of the following case, the notes of which

have been kindly sent me by Dr. G. J. Townsend, of Natick, with whom I saw the patient in consultation.

#### PEDUNCULATE FIBROID COMPLICATING PREGNANCY AND LABOR: DELIVERY BY FORCEPS: SPEEDY ABSORPTION OF THE TUMOR.

CASE III. Mrs. J. P. S., of Natick, aged thirty-eight years; four years married; primipara; menstruated last in February, 1882. In April she noticed a lump in the left iliac region, which, after some overexertion, became painful and tender to the touch. In the latter part of May, Dr. Townsend was called in, and found an irregular nodular mass in the left iliac region, rising nearly to the crest of the ilium; the body of the uterus could not be felt. Pregnancy was suspected. I saw her on June 5th, and could recognize nothing definite but a fibroid tumor crowding the body of the womb, which was soft and indistinct, to the right side. The development of the tumor had, however, been far too rapid to accord with the clinical history of such growths. From this fact and the absence of menstruation, I had no hesitation in endorsing the previously expressed opinion that she was pregnant, and to give the assurance that no special danger was to be apprehended at the time of labor, owing to the fact that the tumor was manifestly subperitoneal and attached to the fundus of the uterus. The tumor increased greatly in volume as the pregnancy advanced, finally reaching as high as the margin of the ribs on the left side, and pushing the body of the womb to the right side. A pedicle running to the left horn could then be made out by Dr. Townsend. She experienced no inconvenience during pregnancy, except from undue distension of the abdomen. The labor, at full term, was tedious, owing to uterine inertia, finally necessitating a resort to forceps by Dr. Townsend. Convalescence was normal, except for an attack of cystitis. Involution was perfect, and no trace of the tumor could be detected three weeks after delivery. The patient is now (February 17, 1885) in perfect health.

Brief notes of another case which occurred in his practice have been sent me by Dr. Townsend.

#### MULTIPLE FIBROIDS COMPLICATING LABOR.

CASE IV. Mrs. J. S., aged forty years, primipara, was found by Dr. Townsend to have multiple subperitoneal fibroids in the fundus uteri when he was called to attend her in labor. Delivery was effected easily without interference. Involution was normal, and the fibroids had entirely disappeared two weeks after delivery. She is still living, at the age of seventy years.

This freedom from interference by the tumors with the normal course of pregnancy and labor I have learned to regard as the rule when the tumor has its seat in the body of the womb, so that it rises with the fundus out of the pelvis and thus presents no obstacle to the delivery of the child. I have had several such cases, of which the notes are now lost—or rather buried in the records of my dispensary. One private case I can quote.

**FIBROIDS COMPLICATING PREGNANCY AND LABOR:  
NORMAL DELIVERY: SUBSEQUENT DISAPPEARANCE  
OF THE TUMOR.**

CASE V. Mrs. G. W. M., of Newton, aged thirty-six years, who had had six children and two miscarriages, was sent to me on April 17, 1878, by the late Dr. Allston W. Whitney, of West Newton. Since the birth of the last child, three years before, there had been some enlargement of the right side of the abdomen. She had not menstruated for six months. The vulva was found to be enormously distended by varicose veins. The abdomen contained a tumor, rising from the pelvis to an inch above the navel. Its general outline was symmetrical, but just above the navel projected a hard rounded mass as large as a fist, and a second small hard nodule below the other, and further to the right still a third. The rest of the tumor is soft and manifestly the pregnant uterus, within which the fetal parts can be distinguished. The hard projecting masses are plainly fibroids. The woman was delivered without mishap on August 1st. On October 28th she visited me again, as the abdomen had remained greatly distended ever since the labor, and she feared that the tumors had not been absorbed in childbirth, as I had assured her would be the case. On examination I found that the distension was entirely due to relaxation of the abdominal walls and to flatulence. The uterus was in every respect normal. There was no trace of the fibroids.

In the later months of pregnancy the difference in density of a fibroid and the pregnant uterus is generally so marked as to make the diagnosis simple; the same cannot be said of a fibro-cyst. Such I now conjecture to have been the tumor in the following patient whom I did not see when pregnant.

**CYSTIC TUMOR, DIAGNOSTICATED AS OVARIAN: SUBSEQUENT PREGNANCY AND DISAPPEARANCE OF TUMOR AFTER LABOR.**

CASE VI. Mrs. E. P. M., of Malden, was sent to me by Dr. Alonzo Towle, of that city, on October 27, 1878. She was thirty-one years of age, had been married eleven years, but had never been pregnant. The lower part of the abdomen was filled with a tumor resting upon the brim of the pelvis and rising as high as the navel. The uterus was retroverted, of normal size, and seemed to move independently of the tumor. The wave of fluctuation could be obscurely felt throughout the abdomen. The diagnosis was an ovarian cyst, as had been Dr. Towle's previously.

A year later this woman became pregnant, was delivered on July 12, 1880, by Dr. Towle, by forceps, owing to a large fetal head and a small pelvis; the child weighed twelve pounds, but lived only four hours. The woman made a good recovery, and at the end of the fourth week no tumor could be found, and there had been no recurrence when the patient was last seen by Dr. Towle, in January, 1882.

The disappearance of the tumor after delivery leads me to change my diagnosis, for I believe that an ovarian tumor would not have been dissipated as a result of pregnancy, whereas it is the rule with fibroids. I believe it to have been a soft fibroid or

fibro-cyst; it might have been a cyst of the broad ligament which ruptured during labor and did not recur; an ovarian tumor it could not have been.

**TWO FIBROIDS COMPLICATING PREGNANCY: MISCARRIAGE AT THREE AND A HALF MONTHS.**

CASE VII. Mrs. K. McH., aged thirty-three years, was married on April 12, 1882, having ceased to menstruate a few days before. She consulted me on July 27, and reported not having menstruated since her marriage. For six months she had noticed a lump in the left side of her abdomen, which had of late increased rapidly in size, and within a few days had become sore. Micturition was frequent; she had nausea. Examination disclosed a fibroid tumor as large as a coconut in the left side of the abdomen; in the right iliac region was another as large as a plum. The vaginal entrance revealed a very characteristic blueish discoloration of pregnancy. The cervix was soft, as was the body of the womb felt through the anterior vaginal wall. The diagnosis of pregnancy at three and a half months, complicated with an interstitial fibroid in each horn of the womb, was unequivocal. I prescribed viburnum and cannabis indica.

On August 1st, she reported having passed something that "felt like an egg" and was followed by some hemorrhage.

On August 14th, I removed a foul placenta, after which the hemorrhage soon ceased.

She had a normal convalescence. The smaller tumor entirely disappeared within two months, perhaps owing, in part, to ergot and muriate of ammonia. The larger tumor remained unaltered in size; still, on January 12th, the uterine cavity measured but three inches in length.

On April 17, 1883, she reported having had no menstruation for two months. The tumor was no larger than formerly. There was no evidence of pregnancy, yet it was suspected. Since then I have been unable to trace her.

**SEPTICÆMOUS FIBROID IN PELVIS COMPLICATING LABOR: TRANSVERSE PRESENTATION: DELIVERY BY VERSION OF STILLBORN CHILD: PROTRUSION OF FIBROID THROUGH THE OS: DEATH FROM SEPTIC POISONING.**

CASE VIII. Mrs. E. D. R., aged forty years, who had had one child seven years before, consulted me on March 22, 1881, with the statement that it was five weeks since she had menstruated; there was no evidence of pregnancy except a very marked blue tinge to the vaginal entrance. The uterus was enlarged considerably by an irregular hard mass, manifestly a fibroid. On April 22d, the uterus had increased greatly in size, was triangular in shape, the left horn reaching nearly as high as the umbilicus. Pregnancy was diagnosed.

As the patient lived in Somerville, I requested Dr. W. W. Dow, of that city, to take charge of her confinement. The subsequent notes are mostly supplied by him.

On December 6th, labor-pains set in, but were feeble until the evening of December 8th, when the os was partially dilated; the child's left side presented, the head lying in the left side of the womb; the fibroid occupied the right half of the pelvic

cavity. At 9 p.m. the patient was etherized by Dr. W. A. Bell, and the os slowly dilated by Drs. Dow and Bell. Dr. Dow then passed his hand into the uterine cavity round the fibroid, which was larger than the fetal head at full term. First the left and then the right foot were successively seized and brought down into the vagina, and after continuous traction, supplemented by external pressure, a stillborn child weighing eight pounds was delivered. Ergotin was injected subcutaneously. The placenta came away spontaneously in fifteen minutes. Very little blood was lost. The uterus contracted well. The fibroid, which had a broad attachment to the right side of the uterus, completely filled the dilated os and projected into the vagina as though in process of extrusion.

During the next three days ergot was administered and the vagina frequently washed with carbolized water.

On December 12th, the lochia became offensive and the pulse rose to 106 and the temperature to 101.4° F.

December 13th, 14th, Pulse 112	Temperature 102° F.
" 15th, " 118	" 103° F.
" 16th, " 120	" 101.6° F.
" 17th, " 120	" 102.4° F. Diarr.
" 18th, " 120	" 104° F. Chill.

An intrauterine douche of carbolized water was carried past the fibroid, which had retreated from the vagina but still plugged the os, to the fundus.

December 19th, pulse 118. Temperature 103.2° F. Intrauterine douches.

I saw her that evening and washed out the uterine cavity thoroughly with a solution of permanganate of potash, and advised an increase of the quinine to twenty-grain doses.

December 20th, Pulse 116	Temperature 102.4° F.
" 21st, " 120	" 102° F.
" 22d, " 112	" 100.4° F. Chill.
" 23d, " 120	" 102.4° F. Chill.
" 24th, " 126	" 101.1° F. Chill.
" 25th, " 120	" 103.6° F. Chill.

I saw her again and suspected septic peritonitis from the abdominal distension.

December 26th, 7 A.M., Pulse 98	Temperature 100.2° F.
" 10 P.M., " 118	" 105.2° F.
" 27th, " 126	" 100.2° F.

Patient is evidently failing.

December 28th, 7 A.M.,	Temperature 100° F.
" 6 P.M., "	" 101° F.
" 29th, 7 A.M., "	" 100.2° F.
" 6 P.M., "	" 103.2° F.
" 30th, 7 A.M., "	" 100.4° F.
" 6 P.M., "	" 103.2° F.
" 31st, 12 M., "	" 90.5° F.
" 6 P.M., "	Death on twenty-third day of childbirth.

The intrauterine douche was administered every six hours during the last two weeks of her life.

At the autopsy the uterus was found to be but little involuted, and contained a fibroid tumor eight inches in length by five in transverse diameter, deeply imbedded in the uterine wall just above the inner os on the right side, and projecting into the cervical canal, distending it as low as the external os. The surface of the tumor was superficially gangrenous, as was the whole lining membrane of the uterine cavity. It did not seem as though any attempt at enucleation of the tumor during childbirth could have been crowned with success.

The notes of the two following cases have been

kindly sent me, with permission to incorporate them in my paper, by Dr. Emma Call, of this city.

#### SUBPERITONEAL FIBROID COMPLICATING LABOR: SEPTIC INFECTION: RECOVERY, WITH COMPLETE DISAPPEARANCE OF THE TUMOR.

CASE IX. Mrs. A., aged twenty-four years, primipara. Previous to her pregnancy she had been treated for cervical catarrh by Dr. Lucy Sewall, who had recognized slight enlargement of the womb but no tumor.

On November 27th labor set in, when a solid subperitoneal tumor, the size of a fist, was discovered projecting from the anterior wall of the uterus. The presentation was normal, but the pains were feeble and the patient exhausted, so that delivery was terminated by means of the forceps applied when head had reached the pelvic outlet. The expulsion of the placenta was followed by a severe hæmorrhage.

For the subsequent six weeks the patient had a mild form of septic infection, not attended by chills. The temperature ranged from 99° F. to 101°. The lochia were profuse and offensive for a few days, until treated by douches and suppositories of eucalyptus. The uterus was tender, especially about the tumor, and there was some effusion into the cellular tissue on the left side. Involution was tardy, so that the patient did not leave her bed for three months, when the uterus was no longer tender and the tumor was half its former size. A year later no trace of the tumor could be detected. She is now well advanced in her second pregnancy, but, having removed from the city, is no longer under observation.

#### SCHEMUCOUS FIBROID AND ALBUMINURIA COMPLICATING LABOR: SEPTIC POISONING: RECOVERY, WITHOUT DISAPPEARANCE OF THE TUMOR.

CASE X. Mrs. B., aged thirty-six years, primipara, three years married. A year previous she had had a sudden severe hæmorrhage. Menstruation had always been profuse. During the last month of pregnancy her limbs were oedematous, and the urine contained much albumen and a few hyaline casts. The quantity of urine was normal, and she only suffered from insomnia.

On January 16, 1885, labor began at midnight; the membranes ruptured at 4 A.M. January 17th, Dr. Call found the head presenting. But little progress was made in the next twelve hours, so that, after consultation with Dr. Lucy Sewall, the forceps were applied while the vertex was lying transversely in the pelvis. In spite of efforts to the contrary, the occiput rotated into the hollow of the sacrum and was with difficulty delivered. The child was stillborn. After delivery of the placenta, the uterus not contracting satisfactorily, a hot intrauterine douche was given, when a solid sessile tumor, the size of a goose's egg, was discovered projecting into the cavity from the posterior wall of the uterus. During the first week of childbirth the patient was nervous and sleepless, the pulse quick, the temperature ranging from 99.5° F. to 101°. The urine was highly albuminous, the bladder irritable. The lochia were normal, except for slight

fetor on third to fifth days, which was corrected by douches and iodoform suppositories.

On the tenth day there were two severe chills; the fundus was three fingers' width above the pubes. There was slight tenderness to the left of the uterus per vaginam. The lochia were scanty and purulent, but not foul. From January 25th the patient presented the usual symptoms of septic infection, the temperature ranging from 103° F. to 105°, the pulse 108 to 120.

On January 29th, Dr. John P. Reynolds and Dr. Sewall saw the patient in consultation with Dr. Call, and confirmed the diagnosis.

On February 1st, the symptoms began to abate, and had entirely subsided by February 10th.

On March 1st, Dr. Call found the uterus still larger than normal, with unusual prominence of the posterior wall.

On March 3d, the patient began to menstruate. The flow was moderate and without pain, but lasted eleven days.

The results of these ten cases of pregnancy and labor complicated with fibroids may be thus summarized:—

Miscarriage . . . . .	1 case.
Recovery of Mother . . . . .	7 cases.
Death " . . . . .	2 "
Living Child . . . . .	7 "
Stillborn Child . . . . .	2 "

With regard to miscarriage, it has been shown by Lefour<sup>5</sup> that this effect of the complication of pregnancy with fibroids is not so common as might be expected. In 227 cases which he cites, miscarriage occurred but thirty-nine times, which is once in 5.82 cases. These figures show no more liability to miscarriage than in cases of pregnancy uncomplicated with fibroids.

The prognosis for the mother, indicated by my cases, is much better than is warranted by the accepted statistics. Thus Lefour<sup>6</sup> states that in 286 cases, including those women who miscarried as well as those who went to full term, 141 mothers died, which is one in 2.02 cases. W. Süsserott<sup>7</sup> states that, in one hundred and forty-seven cases which he compiled, seventy-eight mothers died=53%.

The rates of mortality for the mothers, above cited, I believe to be much higher than we should have were all cases to be reported, it being manifest that those cases presenting no serious results are often thought unworthy of publication.

With regard to the children, Lefour found that of fifty-two infants, thirteen were deadborn. Süsserott states that of one hundred and thirty-eight (including one case of triplets and two of twins) children, forty-seven only survived=34%.

Regarding the position of the child at time of labor, my cases show seven presentations of the head and two transverse presentations. Lefour shows that in one hundred and two cases there were fifty-two presentations of the head (50.98%), thirty-three of the breech (32.35%), and seventeen of the trunk (16.66%). A much larger proportion of anomalous presentations is thus shown by a com-

parison of the figures with those published by Depaul,<sup>8</sup> who had, in a total of 16,233 labors of all kinds:—

15,119 presentations of the head	= 93.1 per cent.
633 " " breech	= 3.9 "
189 " " trunk	= 1.16 "

In each of my two cases of transverse presentations the tumor partially filled the pelvis, so that a transverse position of the child must almost of necessity have occurred. This should be borne in mind by obstetricians in the management of such cases.

With regard to the special complication of labor induced by the presence of the tumor, the above cases illustrate the frequency of inertia of the uterus and the liability to septic poisoning in childbed. This latter danger is hardly mentioned by the authors above quoted; but this omission on their part is attributed to the new views of the pathology of childbed which have come to prevail since the cases occurred of which their compilations are largely composed.

The presentation of a large tumor at the external os, as in case VIII., immediately after delivery, would seem to be almost a unique observation, though several cases are cited in which a tumor thus presented in the later days of childbed. As septic poisoning, with fatal result, occurred in this case, when no attempt at enucleation was made, it may be fairly doubted whether an operation would not have determined a different issue. The post-mortem condition, however, seemed to confirm our previous belief that any operation for removal of the tumor would have been very difficult, very bloody, and, if successful, have left an immense wound for the absorption of septic matter.

The degree of danger to which the woman is exposed in these cases undoubtedly depends greatly upon the precise location of the tumor. Thus in cases II., III., IV., V., VI., and IX., the tumors appeared to be subperitoneal, and all passed through labor and childbed without complication, except for slight septic infection in case IX. In cases I., VIII., and X., the tumors were submucous, and two died, while the third recovered after septic infection in childbed. The location of the tumor in the lower segment of the uterus, so as to interfere with the delivery of the child, introduces the most serious element of danger during delivery. Should this condition exist, and a vigorous attempt under ether to elevate the tumor from out the pelvis early in pregnancy fail, induced abortion or at least premature labor would be the safest course to pursue.

Regarding the effect of pregnancy and labor upon the tumors, my cases demonstrated, in accordance with the accepted teachings, that the tumors increase enormously in size with the progress of the pregnancy. After labor, however, the current belief is that the tumors return to the size from which they started before pregnancy. That this is an error would seem to be made clear by the fact that, in six of the eight patients who survived, no trace of the tumors could be found postpartum, at observations recorded after an interval varying from two weeks to twelve months respectively (cases II., III., IV., V., VI., IX.). In case VII., in which

<sup>5</sup> Les fibrolies utérines au point de vue ni grossesse et de l'accouchement. Paris, 1890, p. 91.

<sup>6</sup> Loc. cit., pp. 218-220.

<sup>7</sup> Beiträge zur Gynäkologie mit 11 neuen myomen complicierten Gebürten. In: Diss., Rostock, 1879, p. 49.

<sup>8</sup> Lefour. Loc. cit., p. 129.

miscarriage occurred at three and one-half months, one tumor was entirely absorbed, and the other was unaltered in size. In case X. the tumor was sessile and only as large as a goose's egg, but appears not to have been absorbed.

The above experience would seem to warrant the following deductions, which do not make a part of the doctrines hitherto prevalent upon the subject:—

As aids to *diagnosis*, the following points should have great weight:—

(1) An area of flat percussion beyond the limits of the tumor or tumors.

(2) Unduly rapid growth of a fibroid.

(3) Bluish discolorations of the vaginal entrance.

As to *treatment*:—

(4) That intrauterine disinfectant douches should be administered throughout the puerperal period in all cases, even before the supervention of symptoms.

As to *prognosis*:—

(5) That fibroids are, as a rule, absorbed during involution of the uterus or soon after.

### THE INFLUENCE OF OVIARTOMY ON SURGERY.<sup>1</sup>

BY JOHN ROMANS, M.D., OF BOSTON.

THE privilege of addressing an assemblage of men engaged in the same pursuit, and having a sympathetic feeling for each other's endeavors to relieve suffering and lengthen human life, is one which I highly prize.

An audience furnished as this is from the annual meeting of the members of the Massachusetts Medical Society is a sympathetic audience which it is a pleasure as well as an honor to address.

I shall not undertake to enumerate in detail all the operations which have followed the habitual performance of ovariectomy and the familiarity with the peritoneum that this implies. I will, however, later on enumerate many of them and narrate at length some of the most striking.

Many of the gentlemen present to-day will remember that not very long ago the distinction between surgery and medicine, or rather between a surgeon and a physician, was that the former dealt with maladies and diseases on the outside of the body, and the latter with those affecting the internal organs,—the principal exceptions to this rule being in the case of foreign bodies in the bladder or air-passages. At the period referred to there were no special courses except on ophthalmology. Now the manner of teaching the science and practice of medicine and surgery has changed and developed so much, particularly during the last ten years, that one in search may find somewhere a special course on almost any subject connected with medical or surgical knowledge. Among the branches of practical surgery none has made greater strides, or been more fascinating in its performance, than abdominal surgery. Twenty-five or thirty years ago, the interior of the abdominal cavity, except to an occasional ovariectomist, or to a performer of Cesarean section, was a *terra incognita*, and not only unknown, but feared and dreaded. The occa-

sional, I had almost said every-day, occurrence of stabs in the abdomen letting out the intestines and followed by recovery, taught surgeons nothing in regard to the harmlessness of simple incision of the peritoneum, and each case was treated with dread, and the rapid convalescence was recorded with wonder and reported as extraordinary. Still more severe injuries, caused by stakes or pitchforks penetrating the abdomen, only served to cause the instruments of these wounds to be preserved in museums, and the patients to be exhibited as surgical curiosities. No one saw and acted on the evident truth that a simple incised wound of the abdominal parietes was almost innocuous. This dread of the peritoneum was caused partly by the experience of surgeons in herniotomy delayed too long, or by seeing peritonitis and death follow a wound of the peritoneum made in a vaginal surgical operation; and by the experience of physicians in autopsies following septic peritonitis after childbirth, in which the intestines were found of a deep purple color and glued together by lymph and pus. All these experiences made the surgeon of twenty-five years ago fear to wound the peritoneum, and held him back from opening it voluntarily and exploring its cavity. To look back now on the long list of recorded cases of men who were found in the streets with incised wounds of the abdomen, and whose intestines, covered with dirt, were carefully washed and replaced within the belly and kept there by sewing the wounded walls together, and who almost invariably recovered, makes us wonder that some one did not see that, if this class of wounds was followed by recovery, how much more likely were wounds carefully made by a cleanly surgeon to unite and heal up!

The literature of abdominal surgery is to-day so voluminous that one man can scarcely read all that comes out in the periodicals alone. The operation of abdominal section, or opening the peritoneal cavity by an incision, has been called laparotomy, from the Greek word *lapara*, which means the soft parts of the body between the ribs and hips, and *tomos*, an incision.

Such words seem pedantic at first, but laparotomy is more concise than "abdominal incision," and we may as well use it. In the textbooks before 1850, ovariectomy is only alluded to, and laparotomy, for the purpose of learning what the trouble was inside the belly, was not dreamed of. I never saw ovariectomy done in this city before I did it, and when I studied medicine here it was not mentioned in lectures or in recitations on practical surgery, and its performance was discontinued and discouraged by the highest surgical authorities in this neighborhood. Dr. Gilman Kimball, of Lowell, however, had been for many years practising ovariectomy in New England, and pursuing his work with great courage and enthusiasm. But by the profession generally the operation was not regarded favorably. Dr. Burnham, of Lowell, was also operating, and in other parts of the United States Atlee, of Pennsylvania, and Peaslee, of New York, were active ovariectomists. Spencer Wells, of London (now a baronet, Sir Spencer Wells, on account of his triumphs in ovariectomy), had taken up the subject on his return from the Crimean War, where he had

<sup>1</sup> Read before the Massachusetts Medical Society, June 10, 1885, and recommended for publication by the Society.

served as a surgeon, and between 1858 and 1864 had operated one hundred times with thirty-four deaths. Although this was a high mortality, yet Sir Spencer proved conclusively that the operation was not only justifiable but imperative.

To Mr. Charles Clay, of Manchester, England, credit is also due for reëstablishing the operation. But I think Sir Spencer Wells's plan of showing all his specimens at Society meetings in London, and reporting every one of his cases, caused the revival and establishment of the operation.

I will not trace the history of ovariectomy, from its first performance by McDowell, of Kentucky, in December, 1809, to the present time; but will enumerate some of the operations and triumphs of abdominal surgery which have grown out of the familiarity with the peritonæum brought about by ovariectomy.

The first operation which followed the removal of ovarian tumors was the removal of fibroid tumors of the uterus. This operation is only to be done in exceptional instances, and its success will probably never equal that of ovariectomy, but the splendid results of Dr. Keith, of Edinburgh—thirty-five cures out of thirty-eight operations—show us what can be accomplished in the performance of this very formidable operation. When it was found that wounds of the intestine, made during an ovariectomy, often united when carefully sewn together, the natural inference was made that intentional wounds of the bowel could also be healed, and this inference was acted on and resection and suture of the intestine for the cure of fecal fistula was successfully done.

Two cases of artificial anus have been cured by this operation by Dr. Porter at the Massachusetts General Hospital within the last eighteen months. It seems very hard, even now, to believe that the intestine can be pulled out of the abdominal cavity, pared, sewed together, and returned, and the abdominal wound completely closed at once and a cure result. But I have myself seen it three times, and seeing is believing. Who does not remember some dreadful sufferer with an intestinal fistula following a strangulated hernia, dragging on a miserable existence, avoiding and avoided, without control over his offensive fecal emanations, solid, liquid, or gaseous. Now to-day ovariectomy has made possible an operation by which this sufferer can be made completely well again.

Laparotomy is done for operations likely to be successful, often or seldom, for cases almost sure to recover, and in desperate cases as a last resort, a forlorn hope. By means of it the spleen has been removed, cancers of the stomach and intestines have been cut out, gallstones have been removed from the gallbladder, foreign bodies from the stomach and bowels, calculi from the kidneys, and even cancerous and diseased kidneys have been excised. The pain and discomfort from floating kidneys has been relieved by sewing the kidney to the abdominal parietes and fixing it in place. All of these operations have been successful in numbers of instances. Perhaps one of the most remarkable instances of successful abdominal surgery is the recent case of Dr. Bull, of New York, who opened the abdomen in a case of pistol-shot wound, found seven perforations of the bowel, sewed the holes

together, and cured the patient completely. I saw Mr. Thornton last summer, in London, lay open the stomach and remove a mass of hair shaped like a sausage and nine inches long by two thick. After the removal of this mass, the wound in the stomach was very carefully and patiently sewed together, and the woman did not even vomit during her convalescence, which was uninterrupted. It may be interesting to say that the mass of hair was the accumulation of nearly twelve years, during which the woman had swallowed what she combed out each night and morning. Mr. Tait, of Birmingham, has shown that great suffering is caused by pus in the Fallopian tubes, and has cured many cases by removal of the tubes. You would be surprised to see how large these tubes, distended with pus, sometimes become. I have seen them of the size of a cow's horn, twisted and convoluted. Removal of the ovaries for hysteria, for insanity, and for the cure of painful menstruation (Battley's operation) has also been done. The sphere of this last operation should be closely and carefully limited, but in certain cases it is a proper proceeding. Removal of the uterine appendages, to bring about atrophy of uterine growths, is very legitimate and promises well. Laparotomy has been done successfully and unsuccessfully in cases of intestinal obstruction. As the diagnosis of the causes of obstruction becomes more precise, so will its relief by surgery be more certain. Up to the present time the failures, I think, outnumber the successes. Laparotomy is also properly done to ascertain the character of growths within the abdomen when we are ignorant of their nature and uncertain whether we can remove them.

Simple laparotomy, properly done in a healthy subject, has no mortality, or perhaps a very small percentage, and is practically innocuous. *All of these advances in abdominal surgery, all of these triumphs and discoveries in an unknown region of the body, have been caused, brought about, and made possible by ovariectomy.*

Encouraged by the success of operations in the abdominal cavity, the thorax is beginning to be explored, and the practice of surgery will probably be extended in this direction. I might give an account of the rise and progress of ovariectomy, and lengthen the list of abdominal operations which have followed it, and keep your interest and attention for many hours; but I have only tried to give a sketch of the influence of ovariectomy on modern surgery. A list of all the operations born of ovariectomy, which have been done successfully, would be long and tedious, but I will venture to enumerate a few. Enucleation, per vaginam, of the entire uterus for cancer of the body of the organ. (This procedure is still on trial, but in practised hands its reputation will improve.) Removal of the spleen for cystic disease; removal of the gallbladder; cutting into the gallbladder (cholecystotomy); hepatotomy (or incision of the liver) for abscess and for hydatids; nephrectomy (or cutting out the kidney) for calculous pyelitis, for cancer, or for tubercle; nephrotomy (cutting into the kidney) for abscess, or for purposes of exploration. Radical operation for the cure of hernia, by sewing together the pillars of the ring and the sides of the sac.

Laparotomy has also been successfully done for pelvic abscess, for splenic abscess, for acute and chronic peritonitis, for hydatids of the peritonæum, for extrauterine foetation. Supra-vaginal hysterectomy in pregnancy with contracted pelvis (Porro's operation) has been often successful as a substitute for Cæsarean section; hysterectomy for the cure of uterine tumors I have already alluded to. That the abdomen could be opened, and an aneurism of an abdominal artery could be successfully treated, would not have entered into the wildest dreams of the most enthusiastic surgeon a score of years ago, and yet this has been accomplished lately by Professor Loreta, of Bologna. He opened the abdomen and found an aneurism of the superior mesenteric artery; he tried to tie the artery above the aneurismal sac, but found this impossible on account of the adhesions of the sac to the neighboring viscera; by puncturing the sac with a small needle and introducing two yards of fine copper wire he succeeded in producing coagulation and curing the aneurism.

My own operations now number two hundred and seventy laparotomies, of which two hundred are ovariectomies for the removal of cystic ovaries; several are cases of removal of ovaries and tubes for the cure of threatened or actual insanity; a very remarkable case of removal of a fibroid tumor of the abdominal parietes and peritonæum, and other laparotomies in which the abdomen was opened for various reasons.

I may be pardoned for narrating at length another very remarkable instance of the curative influence of an abdominal incision. It is a case of tubercular peritonitis. A single girl, twenty-one years old, feeble, pale and emaciated, with a large belly full of fluid, came to St. Margaret's Home a year ago. It was supposed that she had an ovarian cyst. After she was etherized I saw that the fluid was probably ascitic; but I made an antiseptic (spray) exploratory incision to find out the cause of the dropsy. Much ascitic fluid ran out, and many flakes, masses, and layers of lymph. Tubercular deposits were seen scattered over the peritonæum and bowels. In short, the disease was tubercular peritonitis, as was shown from the gross appearances, and from the microscopic examination of masses of the peritonæum which I cut away. In about two weeks the wound opened spontaneously to allow the ascitic fluid, which had accumulated, to run out. The girl went home at the end of three weeks, and returned to the care of Dr. Tower, of South Weymouth. At the end of four months she had gained considerable flesh, and had a good appetite; occasionally she walked out when the weather was pleasant. All this time the opening in the scar of the abdominal incision had been discharging serum. In February of this year, the catamenia, which had been absent more than a year, reappeared, and have returned regularly since. I learned from Dr. Tower that the wound is now healed, and the general health has improved wonderfully, that she is fat and of good color, and is contemplating matrimony. This is, so far as I know, a unique case, and its treatment and cure are direct outgrowths from ovariectomy.

I have given but a brief sketch of what ovariectomy has led up to, of the successes and triumphs

which the establishment of the harmlessness of opening the peritonæum has achieved, and I have shown that all these successful operations within the abdominal cavity owe their inception and execution to the knowledge gained by the ovariologist and furnished by him to the profession.

"We should count time by heart throbs, not by figures on a dial." We should weigh the results and influences of our work, and not simply count and enumerate our operations.

I care but little for a man's statistics unless I know the character of his work. One may cure all his cases, another may have a mortality of twenty per cent. The former may have an exceptionally favorable series of cases. You cannot judge which has really done the most good, simply by the reported statistics.

But these remarks are foreign to the subject of my address. I only mean to say that on this day, the anniversary of our Society, it would be well for us to weigh our deeds and see what we have accomplished in our lives, and I am sure we should find that we have made immense advances in the treatment of morbid states of the organs within the abdominal cavity; and I think you will all agree with me that to the establishment of ovariectomy we owe all our progress in this direction.

## THE STUDY OF ANATOMY:

ITS POSITION IN MEDICAL EDUCATION IN ENGLAND AND IN AMERICA.

BY G. H. MONKS, M.D.

AN American visiting the English medical schools must be struck with the amount of attention everywhere given to the study of anatomy, not only as an abstract science, but also in its more practical relations to clinical work. It may be interesting to examine the system followed there.

The regular lectures on descriptive anatomy are delivered, as elsewhere, by the professors, and present nothing peculiar. The recitations are, however, so far as I know, conducted almost exclusively by the demonstrators. Quain is the textbook preferred.

Little or no dissecting work is done without the help of some good manual of dissections. Ellis's guide is considered the most reliable and exhaustive; but those of Heath and Holden are also good and are considerably used. The demonstrators spend many hours of each day in the dissecting rooms, demonstrating and examining the students on fresh dissections. Material is so scarce that all sorts of means are used to preserve it; and six or seven or even more students work upon the same body. The student has access to numbers of carefully made anatomical preparations, which have been so selected as to embrace nearly all the important parts of the body.

These are arranged with the special purpose of allowing the student to examine them and study from them to the best advantage. In most cases each structure is carefully labeled with printed tags. Some preparations, however, have no labels whatever, and are intended for purposes of exami-

<sup>1</sup> The bacillus of tubercle was not found, however.

nation, and the student can at any time test his knowledge. Skeletons and bones, upon some of which the muscular attachments have been carefully traced, are also exposed to view.

"Quizzes" form an important feature in anatomical instruction. All parts of anatomy are passed over in review several times with the book, with fresh dissections or preparations.

The necessity for using all these means for learning anatomy will appear more evident when we see what is expected of the student at the central examining board, before which he usually appears at the end of his second year. This examination consists of a written and of a *visu et voce* part. As for the written part no particulars need be given, except to mention that one or more of the questions calls for the description of some dissection. It is worthy of note that the information necessary to answer such questions cannot be gained by "cramming." The student must see in his own mind the exact relation of the parts, so as to be able to decide intelligently what skin-cuts he will make, what structures divide, and what draw aside. The following may be given as examples of this test question: Give the dissection necessary to expose the profunda femoris artery, or the posterior surface of the kidney, or the posterior interosseous nerve, or the great sciatic nerve external to the pelvis, or the parts concerned in inguinal or femoral hernia.

In the practical part of the examination the student must identify bones, assign them to the proper side, state bony connections, and mark in red chalk the muscular attachments. He is called upon to identify parts on alcoholic preparations, or on fresh dissections of special regions, and to answer whatever questions may be asked of him in connection with the same. As examples of alcoholic preparations may be mentioned sections of the brain, the diaphragm from above, the liver from below, the fundus of the bladder, the back of the wrist-joint with tendons, and the ligaments of the knee-joint; and fresh dissections of such regions as the triangles of the neck, the pelvis, the muscles of the forearm, the buttocks (the *glutens maxims* being reflected), the popliteal space or the sole of the foot.

In most cases structures must be recognized by their relations, the neighboring parts of the body being, when possibly, concealed from view. The questions most frequently put are: What is this? If a muscle, what are its attachments and actions? If an artery, where does it arise and what are its branches? If a nerve, what parts does it supply? If a space, what are its boundaries and contents? And so on.

Such is the character of the anatomical study during the first two years, and of the examination which follows it. Thus far anatomy has been presented to the student as an abstract science, pure and simple. He is required from this point on to carry the more practical part of it along with him and incorporate it with his clinical work. He is taught to look at the human body as a whole, and to picture to himself the anatomy of the region which may underly any part of the integuments. In this way his anatomy previously learned with labor and painstaking is clinched and made of real practical use. The fact that anatomy is even harder to

retain than it is to learn is recognized by the instructors. They realize that anatomical facts are isolated and have little connection with each other, and that these facts will be soon forgotten unless brought up again and again during clinical work. The student is therefore taught how to identify on the living body the bony processes, the tendons, and masses of muscle; to mark out the course of all the principal arteries, veins, and cutaneous nerves; to indicate the exact lines for incision in all the usual surgical operations, and to enumerate the parts cut through, the parts to be avoided, the number of arteries he may expect to tie, and so on. So well is he taught that he is expected to be able to tell with a fair degree of accuracy what structures a knife would wound if plunged into the body at any point, in any direction, and penetrating to any distance. At the bedside his anatomical knowledge is continually put to the test, until at last, by dint of much exercise and drilling, he does not fail to view any case in the light of its anatomical bearing, if any there be.

Questions like the following are continually put to him: This patient's femur has been broken transversely just above the knee. Why is a double-inclined plane used instead of a weight and pulley? This man has hemorrhoids. He has also a certain disease of the liver. How might trouble in the liver account for the piles? Here is a boy with an enlarged bursa in the popliteal space. Now, what are the bursae in this region, and do you think this one communicates with the joint? This man here fell from a height upon his head. When he was picked up he was senseless and blood was flowing from one ear. A copious discharge of clear watery fluid followed. Now, why should these discharges indicate fracture of the base of the skull? What course does the pus of a vertebral abscess take to point in the groin? in the buttock? Here is a patient on whom colotomy was performed. Was the peritoneum opened? If not, what anatomical arrangement allows the operation to be done without touching the peritoneum? This boy has a congenital hydrocele. What is the difference between this and the ordinary hydrocele of the adult? Why may a patient with hip-disease complain more of pain in the knee than in the hip?

The examination which follows is conducted on the same general principles as the course of instruction just indicated. On the surgical examination paper one question at least is always devoted to surgical anatomy.

All these examinations are conducted by a central examining board whose members are chosen from the different medical schools. No student can be examined by instructors from his own school; thus favoritism is done away with, and each student is taken on his own merits only. Each school, therefore, simply prepares its students for the examination at the central examining board. The instructors at each school are thus stimulated to take a most active interest in getting as many men as possible through the examination, so as to maintain a good average. Owing to the small average number of students in each school the individual student receives a deal of personal attention from the instructors.

The habit acquired in student-life of associating anatomical facts with clinical work appears to be persisted in by the English practising physicians and surgeons, and they most certainly profit by it. It is almost impossible to compare our American methods of teaching anatomy with those commonly used in England, owing to the great variations in standard in the different American schools. Perhaps the most satisfactory comparison can be made if we take as a standard here the average of the best American schools. And if we make such a comparison it will, I think, appear evident to what extent our methods differ from the English ones in certain appreciable details, especially in regard to examinations, "quizzes," dissecting, and other practical work. We see, for instance, that there is in our system only one *examination*, as a rule, which may be written or oral, seldom both, and never very practical. This examination usually comes at the end of the first year, occasionally of the second. The questions are not generally so selected as to draw out the real practical knowledge of the student. A minimum of fifty per cent. is required to pass. It would be quite possible for most students to get this fifty per cent. by a fair knowledge of the textbook alone. I know of one student in one of our best schools who got a mark of ninety-eight per cent. without ever having seen the inside of the dissecting-room. *Dissecting* itself is not often made a prominent feature. If the student is required to dissect only three parts, few students are willing, and fewer still have the opportunity of dissecting more. In some schools it is only necessary to "take out a dissecting-ticket." It occasionally happens that a student has no opportunity to dissect until the anatomical examination is over, in which case the stimulus to do good work is apt to be wanting. Besides this there is no requirement, and often no encouragement, to dissect with the aid of some good manual. Gray's Anatomy is certainly considerably overrated as a textbook, and as a dissector is much worse. One might overlook the fact that the student has not sufficient opportunities for learning anatomy from dissecting for himself, if *preparations* of good dissections were within easy reach. But the museums which contain such are usually closed to him, except on one or two days of each week when he has the opportunity of looking about for an hour or two. Under such conditions the sight of preparations is apt rather to excite his curiosity and admiration rather than to stimulate and assist him in his work.

Systematic "quizzes," by which the student's knowledge can be continually tested and so conducted as to fit him for his examination, appear to be the exception. By the middle of the first year the student finds that he can learn more rapidly, for the examination at least, by reading his textbook at home than by listening to lectures and demonstrations. Perhaps a certain amount of this "examining" would be justifiable and even desirable, if the student could be examined at short intervals, before preparations or fresh dissections. Such an arrangement would be certainly of more benefit than reading through the text with nothing to make it clear but plates and diagrams. Besides this, the student has the advantage of being obliged to do

the work of explanation himself. In schools where there is only one examination in anatomy the subject is completely dropped when once the examination is over; and there is hardly a single school in which the student is obliged to put *his anatomical knowledge into working shape* in connection with clinical work. Thus it must be evident how much lower is the standard of our system of anatomical instruction than that of the English schools. Should it be considered desirable to raise this standard the first step ought to be made by raising the standard of examinations. In a certain sense the standard of any given department can only be measured by the standard of the requirements, and not by that of the instruction. Especially does the standard of anatomy appear to be low in what might be called its practical aspects. In connection with the early anatomical examination a practical element might be introduced and the students examined, so far as possible, on fresh dissections and preparations. To assist the student in preparing for such an examination, special "quizzes," which may be called "small preparatory examinations," might be given, the museums might be opened, or at least a series of good anatomical preparations be exposed to view. If the demonstrators have no time for preparing such a set of specimens, they might be made by some of the most skilful pupils, paid, if necessary, for their work.

Many of the finest preparations at the Museum of the Royal College of Surgeons in England have been made by a non-professional man, specially hired for the purpose. Later on in connection with clinical examinations each student might be brought in turn before the living body and asked questions about the bony processes, tendons, arteries and anastomoses veins and branches, lines for incision in the usual surgical operations, the parts cut through, etc., the limits of internal organs, and lines for cutaneous nerves. He might be called upon to state what anatomical parts can be seen or felt and what surgical information gained by examination, digital or otherwise, of the different natural openings of the body, mouth, rectum, vagina, etc. Suitable instruction could easily be given for this examination, for it would only be necessary that clinical instructors should lay due stress upon the anatomical bearing of their cases, and that some practical instruction on external or applied anatomy should be given. If, in addition to this, the student is obliged to mark out all the lines for incision in the regular surgical operations, he will be in much better condition to profit by his operative courses on the cadaver later on.

There appears no valid reason why the English student should be better prepared in anatomy than the American, but such is without the slightest doubt the case. It may be said that only a small amount of the practical anatomical knowledge possessed by American surgeons has been acquired from the regular course at a medical school. How much time would have been saved had it been otherwise.

It is but right, in conclusion, to call to mind the advances which have of late years been made in the anatomical department of Harvard University. Not only is the elementary instruction in anatomy more thorough in the lecture and dissecting room,

but in many other ways the students are offered greater facilities for learning. Certain practical courses on regional anatomy, medical and surgical, together with an examination in topographical anatomy at the end of the second year, are new departures, introduced with the evident desire of bringing the subject of anatomy into the position of prominence it deserves.

## RECENT PROGRESS IN OTOTOLOGY.

BY J. ORNE GREEN, M.D.

### OTORRHOEAS IN PHTHISIS.

THE character of otorrheas in phthisical patients has for a long time been recognized as peculiar, both in their beginnings and in their course. The beginning of the disease is painless, the first symptoms noticed being a rapid loss of hearing, soon followed by one or more perforations of the drum-membrane, unaccompanied by any marked inflammatory appearances on that membrane; these perforations rapidly enlarge, the membrane seeming to melt away without signs of ulceration, till often the whole membrana tympani is lost; this process is accompanied by but a slight amount of suppuration. Often the highest degrees of deafness are met in these cases, showing an involvement of the nervous structures as well as the tympanum. Healing in such cases is very exceptional, although it occasionally does occur from local treatment alone, and in other cases from local treatment combined with a residence in an appropriate climate.

The absence of pain, the rapid destruction, the involvement of the labyrinth, and the character of the secretion have led to the suspicion that the disease is a specific tuberculous process, and Nathan<sup>1</sup> has recently investigated a considerable number of cases to determine the presence of the tubercle-bacillus in the discharge. He examined forty cases of otorrhoea of all kinds, and in twelve of these found the bacilli in variable quantities. In eight of these twelve cases examination of the lungs and of the sputa proved the existence of tuberculous disease; in one such an examination was impossible; in the remaining three there were no symptoms outside of the ear pointing to tuberculosis, but caries was found in the ears. In the other twenty-eight cases of chronic and acute suppurations no bacilli were found.

Although these observations of Nathan's seem to show that the presence of the tubercle-bacillus is of value in a diagnostic point of view, Gottstein<sup>2</sup> asserts that such is not the fact; that in undoubted tuberculous otorrheas the specific bacillus is sometimes present and sometimes not present; that its absence by no means justifies the exclusion of a tuberculous origin to the otorrhoea; and that a tuberculous otitis media purulenta resembles the tuberculous diseases of the bones and glands in which it has been proved that the bacilli are present in but a small number of the cases. These observations are based upon his own studies and a review of the literature of the subject.

## EXTENSION OF A TYMPANIC ADHESIVE INFLAMMATION TO THE LABYRINTH.

An affection of the labyrinth as an accompaniment of the very common sclerosis (adhesive inflammation of Politzer) of the tympanic mucous membrane has been so often recognized clinically that the labyrinthine disease is described as part of of the pathological process in most textbooks, although it has not yet been determined whether it is secondary to, or whether it occurs simultaneously with, the tympanic disease. Comparatively few observations, however, have demonstrated anatomically the labyrinthine lesion, and in this connection a recent observation of Moos and Steinbrügge<sup>3</sup> is of interest.

The patient, it may be said, died from a hemorrhage from the carotid artery produced by caries of the petrous bone resulting from acute purulent inflammation of one tympanum. The petrous bone on the other side was also examined, and showed chronic catarrhal changes in the tympanum in the form of adhesions between the crura of the stapes and the niche of the oval and round windows, and also a sclerosis of the mastoid cells, probably referable to a typhoid fever in the previous year. The interesting point was that the labyrinth also showed many changes: there was periostitis of the vestibule, with small hemorrhagic spots and connective-tissue new growths; the membrane of the fenestra rotunda was thickened, and showed a deposit of friable cellular detritus on its inner surface, and a similar mass closed the aqueductus cochleæ; there was thickening of the utricle and the ampullæ, and much brownish-red and yellow pigment in the ampullæ, semicircular canals, and epithelium of the utricle.

## Reports of Societies.

### THE AMERICAN OPHTHALMOLOGICAL SOCIETY.

THE Twenty-first Annual Session of this Society was held at the Pequot House, New London, Connecticut, July 15 and 16, 1885. The President, DR. WILLIAM F. NORRIS, of Philadelphia, in the chair.

The first paper was entitled

#### OPERATION FOR REMOVAL OF DISLOCATED CRYSTALLINE LENS.

by DR. C. R. AGNEW, of New York.

The patient had been blind as long as he could recollect. The iris was tremulous, the lens was opaque and very movable. This eye had been painful for some time and recently the other eye had also attracted attention. The vision in this eye was  $\frac{3}{12}$ .

The operation for the removal was as follows: The pupil was dilated with atropia. The patient was then etherized and cocaine was applied. The eye was secured with fixation forceps. An instrument resembling a two-pronged fork, which was termed a bident was introduced into the vitreous chamber behind the dislocated lens, pressing it

<sup>3</sup> *Archiv of Otolaryngology*, xlii.

forward. The bident transfixed the eye and held the lens in position. Section was then made in the ordinary manner and the lens removed; the eye was dressed with absorbent cotton and a black silk bandage. Antiseptic solutions were used and a four per cent. solution of cocaine was applied twice a day. The eye recovered without any unpleasant symptoms. The ophthalmoscope revealed atrophy of the choroid and retina. The speaker did not claim that all dislocated lenses should be removed, but this instrument facilitated the operation when it was required.

EXTRACTION OF A DISLOCATED LENS BY DR. C. R. AGNEW'S BIDENT,

by DR. DAVID WEBSTER, of New York.

The patient received a blow on the right eye. This was immediately followed by loss of sight. Examination showed that the lens was dislocated. No treatment was recommended at that time. Some months later, pain suddenly appeared in the injured eye. The lens was found to be cataractous and incarcerated in the pupil. Cocaine was applied, but did not relieve the pain. Atropia relieved the pain. Later the lens became loose and was found in the vitreous. The tension was normal. It was decided to remove the lens. The bident was passed back of the lens, pressing it forward. The incision in the cornea was then made and the lens removed with a spoon. The eye was dressed with absorbent cotton and recovered without complication. Vision  $\frac{2}{10}$  with  $\frac{4}{8}$ .

With the bident many eyes may be saved, if the lens can be brought in sight. There is no danger from injury of the ciliary body.

DR. H. KNAPP thought that in these cases there was not much difficulty in removing the lens, which could often be accomplished with the loss of very little vitreous, but the danger came in afterward from inflammatory complications; and where the sight was lost, he thought it better to at once enucleate the eye and thus lessen the dangers of inflammation. He considered the bident which was exhibited to be an ingenious instrument. For the last six or eight years he had not introduced an instrument within the globe to facilitate the removal of the lens. This he was able to accomplish by external manipulation.

DR. WILLIAMS, of Cincinnati, considered the instrument an ingenious and useful one, but in the cases reported he agreed with Dr. Knapp that enucleation was the best procedure.

DR. C. R. AGNEW thought that the bident might also be useful in the removal of foreign bodies from the interior of the eye. He did not acquiesce in the view that enucleation was a simple operation. He regarded it as a serious mutilation.

DR. C. H. WILLIAMS, of Boston, thought that there was another alternative than those mentioned, and that was visceration of the eye, the removal of its contents and closure of the anterior opening with sutures. This he had performed a number of times with success. He thought it better than enucleation. It gives a better stump for the artificial eye.

EXTRACTION OF THE LENS IN ITS CAPSULE.

By DR. B. ST. JOHN ROSA, of New York.

For the past three years the speaker had been in the habit of removing the lens in its capsule, in a large proportion of cases without iridectomy. The use of cocaine has facilitated the operation. He referred particularly to the method of dislocating the lens. The section is made as usual, but large. After puncture and counter-puncture are made, the knife is turned on its back, so that it rests on the iris. The knife is then moved up and down two or three times until the lens is seen to move. Then the section is completed, and then the lens can usually be removed with no loss of vitreous. The manipulations on the cornea are made with one or two spoons. Sometimes after the operation it is rolled under, but in many cases the pupil is circular. The writer had performed the operation between thirty and forty times, and is satisfied with his success. If the lens is not dislocated, iridectomy may be performed and the ordinary operation practised. A paper on the subject is to be found in the Transactions of the New York State Society, and in the *Medical Record* for February, 1885.

DR. GEORGE C. HARLAN, of Philadelphia, reported two cases of

SUBCONJUNCTIVAL LUXATION OF THE LENS.

In the first case no operation was recommended, as vision was good; in the second case the lens was removed. The doctor thought it well in those exceptional cases in which vision remains the operator should think twice before resorting to removal.

DR. O. F. WADSWORTH, of Boston, reported a case of

DISLOCATION OF THE LENS UNDER TENON'S CAPSULE.

The eye had been injured two weeks before the patient came under observation. There was loss of sight, pain about the eye, and irritation of the other eye; the cornea was hazy, and there was blood in the anterior chamber. The eye was enucleated, and it was found that the lens was beneath Tenon's capsule, and that it was held in this position by inflammatory tissue.

TREATMENT OF PURULENT CONJUNCTIVITIS.

By DR. J. A. ANDREWS, of New York.

The treatment is based upon the belief that the contagious element is the micrococcus variety. He related a case in which he had secured an inoculation of the seventh generation of a pure culture of a gonococcus. This is the first case inoculated with the gonococcus. He showed an instrument which he had devised to wash out the conjunctival cul-de-sac. It consisted of an eye-speculum with hollow arms, through which fluid may be passed. He had found bichloride of mercury solution (1 to 10,000) serviceable, but apt to irritate. A six per cent. solution of boracic acid was also found efficient. A two per cent. solution of carbolic acid is useful, as it inhibits the movements of the white corpuscles. Irrigation should be maintained for ten minutes, in order to remove all secretion. Nitrate of silver solution (two to twelve per cent.) is then used, and an antiseptic dressing is next applied. This consists of vaseline and boracic acid or carbolic acid, but he laid especial stress upon the importance of maintaining irrigation of the conjunctiva by means of the instrument referred to above.

## ABSCESS OF BOTH FRONTAL SINUSES.

By DR. CHARLES S. BULL, of New York.

The patient had been hit on the forehead, fourteen years previously, with a piece of wood. This produced a fracture of both nasal bones and deviation of the septum. In seven weeks the wound had closed. Ten years after the accident a swelling was noted at the upper inner angle of the right orbit, which could be made to disappear by pressure. There was complete ptosis. An incision was made into the swelling just beneath the orbital margin, and a large quantity of pus escaped (two or three ounces). The cavity was washed with a five per cent. solution of carbolic acid. No communication with the superior nasal meatus could be detected, but the bony septum between the two frontal sinuses was absorbed, and both sinuses were converted into large cavities. The entire ethmoid bone was an immense cavity, the bony structure being absorbed. A number of osteophytes were removed. A drainage-tube was introduced. The patient was discharged six weeks after the operation, and recovered completely. The ptosis disappeared, and the eye was restored to the normal plane.

Dr. KNAPP recommended the substitution of a silver tube for the rubber drainage-tube usually employed.

A case of "Melanotic Sarcoma of the Orbit" was reported by Dr. BULLER, of Montreal, Canada.

## BONY TUMOR OF THE ORBIT.

By DR. B. E. FRYER, of Kansas City, Mo.

The patient, a boy six years of age, came under observation in April, 1885. There was swelling of left orbit, which included the whole line of the superciliary ridge. It was quite hard. Some time before the boy had been struck by a piece of wood, but it was thought that no splinter had lodged beneath the skin. It was decided to remove the tumor, and on examination it proved to be a bony cyst, within which was a small piece of wood. This was enclosed in bone on all sides. The edges of the wound were brought together, and healing resulted without complication.

Dr. W. H. CARMALT, of New Haven, Conn., reported the case of a child of ten years of age, from whom he removed a small growth from the upper lid. Six weeks later the growth had returned. An exploratory operation was done and it was found that the growth extended into the orbit and that it was impossible to remove it entirely. It was therefore decided not to complete the operation. The child has since died; the tumor proved to be a rapidly growing sarcoma. He thought that, if in young children the tumor appears to be quickly recurrent and not easily isolated, no operative interference should be attempted.

Dr. KIPP, of Newark, thought that in many cases these tumors of the orbit are not primary, but secondary, and that the primary tumors may be in such a position as not to attract attention.

Dr. HARLAN, of Philadelphia, reported several instances of inflammatory exudations in the orbit simulating tumors and illustrating the importance of exercising great care in diagnosis.

Dr. W. S. BENNETT, of New York, exhibited a series of new test-letters.

Dr. NORRIS, of Philadelphia, presented a new sheet of metric test-letters, devised by Dr. Oliver, of Philadelphia.

Dr. C. R. AGNEW, of New York, made a brief reference to a case of occasional or simulated blindness in which the vision suddenly returned.

Dr. THEOBALD described a similar case, in which there was sudden blindness. The pupil acted normally and the ophthalmoscope revealed no disease. A favorable prognosis was given and the patient recovered sight in a short time.

Dr. BULLER, of Montreal, thought that these cases could not be properly termed entirely imaginary. He thought that there was, for the time being, a functional loss of power in the nerve. He referred to a case in which there was hysterical blindness and deafness associated with loss of sensation in the skin covering the mastoid region. On one occasion, he applied to the anæsthetic surface an iron sufficiently hot to raise a blister. This was done without the patient's knowledge and unexpectedly. But it did not cause her to wince.

Dr. ROOSA had been led to believe from his experience that in these cases there is a basis for the blindness in the ocular condition. There is a derangement of sight from some condition and the patient finally imagines that she is blind.

Dr. HARLAN thought that there were two classes: one in which there is purely deception, perhaps the result of deranged mental condition; and a second, in which there is real temporary suspension of function.

Dr. RISLEY, of Philadelphia, thought that some of these cases might be explained by an enfeebled condition of the circulation, in which the heart was unable to force the blood against the normal intra-ocular tension, and the loss of vision thus results from want of nourishment of the retina.

Other cases of hysterical blindness were described by Dr. WILLIAMS, of Cincinnati, and Dr. ANDREWS, of New York.

## SOME OF THE RESULTS OBTAINED IN THE COMPILATION OF 1,000 CASES OF REFRACTION.

By DR. E. E. HOLT, of Portland, Maine.

The writer had been in the habit of recording all the measurements connected with the prescribing of glasses. As a result he had found in 1,000 cases thus recorded the average distance between the centres of the pupils of the human eye to be about 60 mm. The average of other measurements was given; and the importance of the physician determining and designating them, and then seeing that they were carried out, was dwelt upon.

## RAPIDLY PROGRESSIVE MYOPIA CHECKED BY SECTION OF THE EXTERNAL RECTUS.

By DR. G. C. HARLAN, of Philadelphia.

The case was that of a boy of sixteen, in whom myopia was progressing rapidly; the external rectus was divided seven years ago. The internal rectus was also exercised by the use of prisms. Since then there has been no increase of the myopia.

## THREE CASES OF PROGRESSIVE ASTIGMATISM.

By DR. SAMUEL THEOBALD, of Baltimore.

Astigmatism of traumatic origin, he remarked, is observed not infrequently to undergo changes in

degree, but it has been commonly held that congenital astigmatism does not alter in degree, though the refraction of the eye as a whole may undergo marked change. The cases which he reported, he thought, proved that there were some exceptions to this rule. The first case was that of a young man, who, with a high grade of hypermetropia, had an astigmatism of each eye, which required for correction a  $+1-200$ . The case was observed at intervals during a period of twelve years and during that time the astigmatism increased until finally a  $+1.3$  C. was needed to correct it.

The second case was one of compound myopic astigmatism in a young man, in which there occurred, along with an increase of the myopia, a growth of the astigmatism during a period of sixteen years from  $\frac{1}{10}$  to  $\frac{3}{8}$ .

In the third case a simple myopic astigmatism in a physician twenty-five years of age, requiring a  $\frac{2}{4}$  in one eye and a  $\frac{3}{8}$  C. in the other for its correction, changed in five years so that a  $\frac{1}{11}$  C. and a  $\frac{1}{13}$  C. respectively were needed.

The speaker regretted that the examinations had not all been conducted under a mydriatic, as they would then be more apt to carry conviction to the minds of those disposed to be sceptical regarding the progression of astigmatism. He did not believe that the result would have been different. Such cases are not frequent, but it is important that the fact should be recognized. As the increase of astigmatism is probably due to change in the corneal curvature, the phenomenon should be met with more frequently in the yielding myopic than in the relatively stable hypermetropic eye.

#### AFTERNOON SESSION. — HYPERMETROPIC REACTION PASSING INTO MYOPIC REFRACTION.

By DR. S. D. RISLEY, of Philadelphia.

The speaker had on previous occasions called attention to five cases of a similar kind, and the object of his paper to-day was simply to report six additional cases seen within the past year.

DR. W. S. BENNETT, of New York, made a few remarks on the importance of the examination of spectacles. He exhibited a series of drawings showing the effect of different kinds of lenses on straight lines. He also exhibited an electric light ophthalmoscope, a description of which has been printed in the *New York Medical Record*.

An arrangement for the demonstration of refraction and accommodation was exhibited by DR. LEON H. HOWE, of Buffalo, New York.

This consists of two hands of thin metals bent in such a manner as to represent the outlines of a double convex lens and passing through it two jointed rods representing the rays of light ordinarily figured as passing through such a lens and joining at its focus. The flexible bands were attached to each other above and below, so that by approaching or separating the sides they could be made to show less or greater convexity. The rods representing the rays of light were jointed near the centre in such a way that while the two halves could be placed in such a direction as to show the light as entering parallel to the axis of the lens, the other two portions could be bent to a point to show the convergence of rays at the focus. By alteration in

the position of these rods and also in the forms of the bands representing the lens all the different variations of the laws of refraction and the changes in accommodation can be demonstrated to a class.

DR. E. DYER, of Newport, Rhode Island, demonstrated a perimeter which he had described at the last meeting of the Society.

#### TWO CASES OF UNILATERAL TEMPORAL HEMIANOPIA.

By DR. E. S. BULL, of New York.

The first case was that of a man aged sixty-six years, first seen in 1884. In 1849 he received an injury which rendered him unconscious. When he regained consciousness he found that he was blind in the right eye. In 1883, he noticed a central obscuration of vision in the left eye. There was no syphilis, no disease of the heart, and no indication of Bright's disease. He had never used alcohol to excess, but smoked and chewed tobacco in large amounts. There was an irregular central scotoma. The media were transparent and the iris normal. Both optic discs were of a dirty-white color and in both there was a deep excavation with pulsating veins and in the left eye there was a large retinal hemorrhage. The tension was normal.

The second case occurred in a man aged sixty. He had been knocked down by a horse, receiving a depressed fracture of the frontal bone above the left eye. The patient was unconscious or delirious for four weeks following the accident. When he regained consciousness he found that the left eye was blind. Examination showed that in the left eye there was somewhat irregular temporal hemianopia. This may have resulted from fracture of the superior orbital plate, with injury to the fibres of the optic nerve going to the temporal half of the retina.

#### TWO CASES OF PENETRATION OF THE EYEBALL WITH SCISSORS IN THE OPERATION OF STRABISMUS.

Read by DR. H. DERBY, of Boston.

The first case was that of a young man on whom an operation for strabismus had been attempted. The surgeon inadvertently picked up a pair of sharp-pointed scissors. The point of the scissors suddenly penetrated the eyeball and a portion of vitreous equal in size to a cherry-stone escaped. The operation was abandoned and Dr. Derby was called to see the case. The eye was bandaged and the patient put to bed. Several attacks of inflammation supervened, but the patient was discharged on the forty-first day with  $V=7/10$ .

In the second case the scissors also entered the sclerotic, but after a somewhat tedious convalescence the wound was found closed on the twenty-first day, with vision as good as before the operation.

DR. KNAPP stated that he had done three thousand squint operations, and in three cases he had punctured the sclerotic. He, however, completed the division of the muscle, and the patients recovered as readily as from an uncomplicated operation.

DR. MITTENBOM stated that he had been present at a strabismus operation where the sclera was opened. He advised the surgeon to complete the operation. This was done, and the wound healed in four or five days. He thought that, in case the

accident happened, the division of the muscle should be completed.

DR. E. WILLIAMS, of Cincinnati, reported a case in which he had punctured the eye. The patient recovered without difficulty.

**STRABISMUS: ITS CORRECTION WHEN EXCESSIVE AND IN HIGH DEGREE OF AMBLYOPIA.**

By DR. E. E. HOLT, of Portland, Me.

The writer had employed advancement of the weakened, attenuated muscle in connection with tenotomy in certain cases of squint, and after tenotomy alone had failed to correct the deviation. He also exhibited an apparatus he had devised for showing the associated and accommodative movements of the eyes, and the effects of tenotomy and advancement of the muscle in correcting squint.

DR. KIPP at one time employed advancement, but he had given it up because it was difficult to graduate the result.

**THE TREATMENT OF STRABISMUS INTERNUS.**

By DR. W. W. SEELY, of Cincinnati.

He said that early operations (up to the tenth or fifteenth year) are questionable, and possibly should be entirely abandoned. He combated the idea that crossed eyes never became straight without an operation. Nothing is better established than the relation between ametropia and strabismus, and all recognize the necessity for glasses to prevent the recurrence of squint after tenotomy. Every one knows that it is possible to correct the squint by setting aside the ametropia by means of glasses. He said: "My early conviction that something should be left to time and glasses has long since grown into an absolute law of action, for I have become thoroughly persuaded that immediate perfection meant later in life insufficiency or even divergence."

"Operative procedures should not be the first consideration, but should be looked on as an adjuvant to be resorted to later on if necessary."

He summed up as follows:—

(1) That, with our present light, routine operation is wrong.

(2) That to thoroughly correct the deviation in young children by operative interference is extremely liable to subject them in after life to insufficiency or external squint.

(3) That a later period of life, if anything, favors better results from operative interference.

DR. KNAPP thought advancement a dangerous operation. He had always been able to correct the deviation by two or three tenotomies, and, if necessary, stitching the eye to the commissure.

DR. THEOBALD, of Baltimore, endorsed Dr. Knapp's views in reference to advancement. He was surprised at the conclusions of Dr. Seely. Squint operations in his hands had been very satisfactory. If postponed they are likely to prove unsatisfactory, on account of the amblyopia which is liable to be developed.

DR. O. F. WADSWORTH had studied the subject for a long time, and had convinced himself that amblyopia from squint did not occur. The ability of the patient to use the vision which he has does seem to be lost by a continuance of the squint, but it may be recovered by practice. If the examina-

tion of vision was carefully made, he was certain that it would be found that the vision was not improved after the operation. It, however, is often difficult to get the full amount of vision which a squinting eye possesses.

**ECTROPION OF BOTH LIDS: BLEPHORPLASTY BY THE ITALIAN METHOD.**

By DR. R. H. DERBY, of New York.

The displacement of the lids was the result of cicatricial tissue from a severe and extensive burn of the face. The lids were loosened from their attachments, and the new lids formed from flaps raised from the arm. The arm was bound to the head with water-glass plaster, and the pedicle was not divided until union had taken place.

Photographs were exhibited showing the appearance of the patient before and after the operation.

DR. H. DERBY, of Boston, exhibited a box of trial lenses made by Nachet, in which the following features were embodied:—

(1) The doubling of the prisms.

(2) The distinguishing of the cylindrical lenses by coloring the positive settings black and the negative red.

(3) The adaptation of the trial frames to receive the glasses without removal from the patient's head.

(4) The removal of the handles from the prisms and cylinders.

**PLASTIC OPERATIONS WITHOUT PEDICLES.**

By DR. B. JOY JEFFRIES, of Boston.

The object of the paper was to make one or two suggestions which the author had not yet put in practice but which he was ready to try when opportunity offered. He suggested the use of the prepuce from the circumcision of Jewish children for operations about the eyes. He also suggested that in plastic operations the desired result might be obtained without the use of a flap by employing carbolized oil dressings to retard healing, for it is well known that some time after a plastic operation the transplanted tissue has almost entirely disappeared.

Adjourned until evening.

**EVENING SESSION.**

DR. HARLAN, of Philadelphia, reported "Two Cases of Congenital Paresis of the External Rectus."

Dr. Harlan also exhibited and described Borek's sphero-cylindrical lenses.

**THE REMOVAL OF A BIT OF STEEL FROM THE LENS WITH THE ELECTRO-MAGNET.**

By DR. J. L. MINOR, of New York.

M. S. was struck, one week before coming under observation, by a piece of steel. There was a small scar in the cornea and vision was much reduced. There was clearly a piece of steel in the lens, which the speaker desired to remove at once. After consultation it was thought advisable to await the development of some symptoms. The patient was therefore given atropine and instructed to return if the eye gave any trouble. Sometime later the eye became irritable, there was considerable ciliary injection, there was haziness, and the tension was increased. Cocaine was employed and iridectomy

performed. The shank of a strabismus hook was touched to an electro-magnet thus making it a magnet. The extremity of the hook was then carried into the lens and the piece of steel at once attached itself to it and was removed. Thirteen days later the eye had recovered from the operation. The lens has not yet been removed.

#### MALFORMATION OF THE UPPER LID.

By DR. R. H. DEBEY, of New York.

In this case there was a fissure of the upper lid, from the angle of which a portion of skin projected in a peculiar manner.

#### REMOVAL OF EPITHELIOMA OF THE EYELID BY APPLICATIONS OF BENZOLE AND CALOMEL.

By DR. A. MATTHEWSON, of Brooklyn.

O. D., laborer, fifty years of age, was seen October 3, 1881, with tumor on the right lower lid. This first appeared as a warty growth three years previously. Of late it had been rapidly growing and presented a raw granulated surface. Careful examination by an expert showed it to be undoubted epithelioma. It was treated by frequent dustings of calomel, after brushing the surface with benzoole. The tumor entirely disappeared until a few months ago when a granular spot appeared at one edge of the site of the former growth. This disappeared under a renewal of the same treatment.

#### LIPOMATOUS PTOSIS.

By DR. H. S. SCHILL, of Philadelphia.

Under this head the speaker reported four cases of ptosis from excessive accumulation of fat in the upper lids. The condition occurred in young women between the ages of eighteen and twenty-five. The deformity was symmetrical, the weight of the lid causing it to cover one half of the cornea. The excessive fat was removed through horizontal incision. The smallest amount taken away was thirty-five grains, the largest seventy-one grains. The levator regained power in from one to four weeks. In one case it was necessary to repeat the operation.

#### CLINICAL OBSERVATIONS.

By DR. L. WEBSTER FOX, of Philadelphia.

CASE I. Congenital cataract in both eyes successfully operated on in a patient sixty years of age.

H. H., a negro, aged sixty, presented himself at the Germantown Hospital, February 1, 1884. Congenital cataract of both eyes was found. The use of a four-grain solution of atropia produced no dilation of the pupils. There was simply light perception. Shortly afterward the right lens was removed and the wound rapidly healed. At the end of eight days the patient could see but could not name objects without touching them. The lens of the left eye was subsequently removed. The effect of the acquisition of sight after sixty years blindness was carefully described by the speaker. The lenses, when removed, were found to be of a spheroidal shape. The optic nerve presented an oval outline.

CASE II. Recovery of useful vision after eighteen years' blindness.

R. L., aged thirty-seven years, was injured in the

left eye when three years of age. Two years subsequently sympathetic ophthalmia developed in the right eye, resulting in qualitative perception of light only. An iridectomy was done at the Germantown Hospital, in June, 1884. The media were found to be clear. When admitted to daylight complained of erethropia to such an extent that dark glasses were ordered. This disappeared in the course of three months. A +10 D. spherical glass was ordered for distant use, and a +14 rendered near objects visible. Subsequent examination showed that better vision was obtained by a combination of spherical and cylindrical lenses.

CASE III. consisted in the history and treatment of five cases of retinitis pigmentosa by electricity (constant current). There was marked improvement which, in one case, remained nine months after discontinuance of the treatment. Five cells are usually employed, the positive pole being placed over the closed eyelid and the negative pole at the nape of the neck.

#### ON THE PULSATING VARIATIONS OF INTRA-OCULAR TENSION, AS MEASURED BY THE MANOMETER.

By DR. LUCIEN HOWE, of Buffalo, New York.

In calling attention to the variations of intra-ocular tension some attention was also given to various forms of manometer or instruments for its measurement. The earlier forms consisted simply in a U-shaped tube of glass connected by a flexible tube to a trocar. When the trocar was introduced into the anterior chamber of the eye the intra-ocular pressure would tend to force the fluid through the tube and show the degree of pressure by a rise in the opposite column of the U-shaped tube. This was imperfect for the reason that when the aqueous humor escaped from the eye, it was at once in an abnormal condition. The double manometer described by Grasser and Holzke obviated this difficulty. In this, however, there was an imperfection in the trocar, which was rather complicated and liable to get out of order. An improvement was accordingly suggested in having a stop-cock attached to a needle of the hypodermic syringe, and this the writer found to serve the purpose much better than any other. The animal best adapted to this class of experiments is the cat, on account of the deep anterior chamber.

In the earlier experiments with the manometer, it was noticed that the intra-ocular tension varied with the heart's action. In addition to this the writer called attention to the fact that these variations in the pressure, as indicated by the manometer, correspond to pulsations which can be seen with the ophthalmoscope in the vessels in the interior of the animal's eye. In other words, if the same thing hold in the human subject, we must infer that when pulsation is seen in the interior of the eye there is also a variation of intra-ocular tension. Although not enough to be detected by the touch or by an ordinary instrument, this connection between pulsation and pressure is a demonstration of the cause of venous pulse in the eye as explained by Donders. It was also observed that, after the introduction of the needle, there was at first considerable pulsation, but after a short time this ceased, the eye evidently adjusting itself to the

unusual condition. The experiments referred to were made in the laboratory of Professor Zunzt, of Berlin.

Dr. H. KNAPP, of New York, reported nine successive cases in which the electro-magnet was used for the extraction of chips of iron from the interior of the eye.

These cases were operated upon during the past three and one-half years. In two the chip of iron was located in the iris. In one for two days, causing inflammation, and in the other seventeen years, remaining quietly until recently. Both were successfully removed without deterioration of the eye. In the seven remaining cases the foreign body was in the vitreous, had produced cataract, and could not be seen. In three cases the attempt to extract them with the magnet failed and the eyes had to be enucleated. In four cases the chips of iron were brought fourth at the first, second, or third introduction of the tip of the magnet. In all these four cases the recovery was smooth. All four are still cataractous. In two the form, size, and tension of the globe is not changed, and the perception of light is good over the whole field. In the two others the globe is slightly smaller and softer and the field of vision defective, corresponding to the wound made for the extraction of the foreign body. There was no irritation in any of the four eyes as long as they were under observation.

#### THE ACTUAL CAUTERY IN DESTRUCTIVE CORNEAL PROCESSES.

By Dr. H. KNAPP, of New York.

The speaker cited a number of cases in which its use had been of service, and considered it a valuable measure.

Dr. Howe had employed this measure in three cases, and the corneal ulcer had been somewhat lessened.

Dr. E. WILLIAMS, of Cincinnati, had for the past fifteen years been in the habit of treating ptyectenular ulcers of the cornea by the application of pure carbolic acid, and had found it to act admirably.

Dr. O. F. WADSWORTH had for several years been in the habit of using carbolic acid for ulcers cornea serpens and for sluggish, painful infiltrations of the cornea. In sluggish infiltration the application is preceded by scraping, and in some cases the simple scraping has been sufficient. When the ulcers cornea serpens had been severe, he did not recall that it had entirely stopped the process. In a recent case in which the acid was applied at the beginning of the affection, three applications checked the disease.

Adjourned to Thursday morning.

(To be concluded.)

### Recent Literature.

*The Inhalation Treatment of the Diseases of the Organs of Respiration, Including Consumption.* By ARTHUR HALL HASSALL, M.D., etc. London: Longmans, Green & Co. 1886. Pp. 357.

This is a timely book. Cohen's last edition was published in 1876, and no complete English work on

inhalation has ever before appeared — a strange fact when one recalls to mind the number of people armed with respirators one meets in the streets in England. It is true that until recently no medicinal substances were used in these machines, which were designed chiefly to warm and filter the air before its entrance into the respiratory passages. But, in England and Germany alike, for several years before the discovery of the bacillus tuberculosis, respiration had been charged with various antiseptics, such as carbolic acid, creasote, eucalyptol, and thymol, with the idea of acting directly on the diseased parts. Among others, Burney Yeo, Curschmann, and Cohen reported favorable results from this practice, which seemed to them to allay cough and diminish expectoration, thus contributing materially to the comfort of the patient. In a paper read very recently by Dr. Beverley Robinson, of New York, before the American Climatological Association, similar conclusions are reached. There is thus a fair amount of clinical evidence in favor of this method of treatment, when properly applied and carried out, as a palliative in many cases of phthisis and some other affections of the lungs. Dr. Hassall, however, shows that there is reason for being very sceptical as to the usefulness of antiseptic inhalations as hitherto practised, four fifths of the total amount placed on the sponge of the respirator being recoverable after the completion of an inhalation lasting one to two hours. The quantity thus brought into condition for absorption would seem to be altogether too small to have much effect; and, even if the volatility of the antiseptic be increased by the addition of chloroform, ether, or alcohol, the case stands but little better. In order that an effective amount of the vaporized drug should be capable of absorption the temperature must be raised or the area of the surface from which evaporation can take place must be greatly increased. For a description of the method adopted by Dr. Hassall to meet the requirements we must refer our readers to his book, or to articles by him in the *Lancet*,<sup>1</sup> describing his inhalation chamber, his globe respirator, and some of his experiments. The inhalation chamber at San Remo is now completed and in use, but we have seen no report of cases illustrating its practical working.

When carbolic acid is thus inhaled "the renal secretion should be watched, and as soon as this becomes decidedly discolored, the treatment should be modified or suspended until the darkening becomes lessened" — until the darkening disappears, we should say. "A watch should also be kept on the general symptoms, including particularly the pulse and temperature."<sup>2</sup> In chapter vii., which, in one hundred and thirty pages, deals with the inhalation treatment of diseases of the organs of respiration, subjects other than that of treatment, and treatment other than that of inhalation, are more or less dwelt upon. The index we have not found as complete as it appears to be at first sight.

In conclusion, the work is one which specialists in the diseases of the respiratory passages must have, and which the general practitioner will oftentimes find useful.

E. C. S.

283 WASHINGTON STREET, BOSTON, MASS.

## PROTECTION FROM DEFECTIVE-VISION ACCIDENTS ON THE OCEAN.

A LEADER in the *British Medical Journal* of June 6th severely criticizes the report of the Assistant Secretary of the Marine Department to the British Board of Trade on "Examinations for color-blindness in the mercantile marine." It closes by saying, "To illustrate these defects, we may point out that the examiners are mainly retired ship-captains, and that the candidate is told to name, at three feet distance, a colored card or glass of about the size of the hand; whereas at sea it may involve fatal consequences if he fail to recognize, at a mile distance, a colored light which itself is not much larger. Moreover, we may mention that four of the candidates who called the *green* card or glass *red* subsequently passed the examination successfully, a course of events simply impossible to such candidates with a fair and intelligently conducted examination. Till these defects are remedied, we cannot agree with the paragraph which winds up the report, that 'if in future any accident arise from color-blindness on the part of any sailor on board any ship it cannot be laid to the door of the Board of Trade.'"

The returns from the Board of Trade to an order of the House of Commons of August 5, 1879, giving the results of only thirty-nine cases of defective color-sense found in two years, *thirteen of whom subsequently passed*, was naturally the subject of scientific ridicule, as have been the "Instructions to examiners" of January, 1877, and May, 1880. Since then the Marine Department has had the benefit of the published government reports from this and other countries, as they state. They also have had before them the resolutions on this subject of defective vision adopted by the International Medical Congress of London, 1881. From the transactions of the Ophthalmological Society of the United Kingdom and the published articles of those members who have interested themselves for a control, it is certain that the Marine Department of

the Board of Trade has had the subject properly and thoroughly pressed upon it, notwithstanding which it makes this extraordinary report of February, 1885, criticized as above by the *British Medical Journal*. Thanks to the exertions of a few experts in this country no such report has emanated from any of the departments of our general government. It would cost the author his position.

This report insists on the sufficiency of asking a person the names of colored objects, cards, or pieces of glass, and even that by retired sea-captains. Mr. Brailey states that one of these examiners gave a rejected candidate the absurd advice that his defect was probably due to biliousness, and that he should come back again after experiencing the potency of a blue pill and a black draught. Have the authorities of the land of Wilson, Poole, and Tyndall not yet got it into their heads that what a person calls colors is no proof whatever of whether he *sees* them correctly. The utter inefficiency of such tests as are required by the Board of Trade by their examiners is shown by the very few reported as defective,—only about one half per cent., as the *British Medical Journal* estimates,—whilst when a thorough test is applied in proper hands, namely, medical men properly taught, at least four or five per cent. are found color-blind. It should be remembered that only masters and mates are tested, and only as to their color-sense. They may be half-blind from disease or nearsightedness, etc., as the English experts have repeatedly shown by cases in their hospital or private practice.

This report says: "In some cases in which the examiners decide that the applicant has failed, and in which the applicant holds a contrary opinion, as well as in cases which may, in the examiner's mind, raise a doubt as to the propriety of passing them, the facts are reported to the department with full particulars, and the applicant is *retested* by means of a modification of Hologren's system of colored worsteds referred to in Appendix B." This appendix commences with a description of the colored worsteds to be used, and says: "The test consists in the examiner taking *any particular skein* from a heap of worsteds and requiring an applicant for examination in color to choose out of the heap the other skeins most closely resembling it, and to put them by the side of the sample skein. The best colors to use as sample skeins have been found to be a pale green, a bright red, or a light purple (or violet)." The appendix further states that Dr. Thompson's modification of Hologren's method is generally used, and "the person tested is *shown a skein* and told to throw over the stick all the skeins which, in his opinion, most nearly match it." The italics are ours. And this, we are told in a "Report presented to both houses of Parliament by command of her Majesty," is Hologren's worsted test. The author of the report does not seem to have gathered any idea of what the test really is or how it should

be carried out. Methods and practice are similar to the foolish non-compliance with the law by which one railroad employee tests another. The regulations sound like the twists and turns our United States Board of Steamboat Inspectors have taken to retain color-blind pilots, etc.

Besides, however, the natural ignorance thus exposed which could and should have been overcome by any such body as the Marine Department of the Board of Trade of England, there crops out the same determined prejudice against employing proper expert examiners as our communities have had to contend with here. The report says: "In the interests of the curious or learned in the matter of color-blindness many suggestions have been made which would have the effect of placing on record peculiarities of vision of a more complicated character than mere inability to distinguish well-known colors; but to extend the examinations for that purpose, though interesting and useful in many ways, would be altogether beyond and apart from the object with which our color-test was established, and would be of no value to us or the applicant. We have therefore abstained from going into any refinements of the sort."

This sounds like an extract from the speeches and newspaper articles when we had "color-blindness in politics" in Connecticut and Massachusetts. In view of the very practical and very simple methods and the low standards recommended by the International Medical Congress and the Ophthalmological Section of the British Medical Society, it is an insult to the medical experts who have urged a control which the Board of Trade admits, and the Civil Lord of the Admiralty, Sir Thomas Brassey, proves, is made necessary by a shipwreck or collision in every four hours round England's coast. The community demands that the color-blind shall be eliminated from posts of danger. Men of knowledge show that this cannot be done except by proper tests in expert hands. There certainly has been no better argument printed proving the need of the International Commission to disseminate a knowledge of the real facts, and agree as to requirements regulating it, than this last Board of Trade report. We are glad to see that those urging our government to initiate such a commission are still active. At the late American Ophthalmological Society meeting at New London it was voted:—

"That the Society would again express most hearty approval of the International Commission twice recommended in a bill by the naval committee of Congress, and endorsed by the International Medical Congress of London, 1881, to consider and agree upon standard colored lights and signals, etc., and the visual power and color-sense of officers and sailors.

"The Society would particularly support the International Congress vote, that every government, especially the maritime governments, should

be requested to place one or more members on the commission, and chiefly naval officers and medical specialists." The Secretary is hereby directed to transmit this note to Congress."

The horrors of the sea are enough, without the unnecessary addition of the chances from mistaking other vessels' lights, or not seeing the shore-signals, not noticing marks, buoys, lighthouses, etc. We wish those striving for control godspeed in their efforts.

#### DR. FERRÁN AND HIS METHODS.

A LAY correspondent of the *Boston Herald* writes regarding the so-called cholera inoculation operations of Dr. Ferrán, and the attempted investigation of them by the Committee of the French Academy. In spite of the government opposition, of which Dr. Ferrán complains, it would seem that he is making a "good thing" peculiarly out of the operation. The correspondent says that he holds regular vaccinating *séances*, at which the attendance is so numerous that he is forced to accept the services of four assistants. His operations have been confined to Valencia, Alcira, and neighboring towns, but in a few days he is going to Madrid. His fixed charge for inoculating is fifty reals (\$2.50), and all day long there is a dense crowd of people at his door waiting their turn. Before entering the operating-room, each person passes in front of a cashier's desk, where a numbered slip is given in exchange for the fee. Those who prove that they are too poor to pay this fee are vaccinated gratuitously; but the poorer portion of the population does not seem to take much interest in the matter, and most of the doctor's patients thus far belong to the wealthy or middle classes who are fully able to pay him. Of these an average of 600 present themselves in his operating-room every day. He and his assistants operate in a large, square room; the operation consists in making, by means of a Pravaz syringe, a hypodermic injection of a cubic centimetre of the vaccinating liquid, and this injection is made in the posterior portion of the patient's two arms. The effects which follow this inoculation are in no way different from those that would follow a subcutaneous injection of any irritating liquid. There is a little redness of the skin, a certain amount of heat and swelling in the surrounding tissues—in short, all the symptoms of a mild local inflammation; the general symptoms are not at all marked—a little feverishness, a slight giddiness, a trifling gastric disarrangement are about all that can be detected. Diarrhea is so rare a result of the vaccination that it probably does not occur in one case out of a thousand. Sometimes the injection causes an abscess, but this seems to be due to the careless way in which the Spanish doctor and his assistants operate. They do not take any more

precautions than they would if they were inoculating a lot of animals.

As is well known, Dr. Ferrán observes the utmost secrecy as to the composition of the culture-fluid. He is said to have admitted to Dr. Gibier that bile entered into its composition, but further than that would say nothing. The French Commission, consisting of MM. Brouardel, Charrin, and Albarran, was, of course, frustrated in its attempt to investigate the scientific value of the operation by ignorance of what was really inoculated. Dr. Gibier, a colleague, who was allowed to examine the virus microscopically in the presence of Dr. Ferrán, said that it undoubtedly contained comma-bacilli, but whether those of Koch, or no, he was unable to say. The air of mystery thrown about the whole matter and the strong commercial spirit shown by the man who, a few months ago, was an obscure country doctor, and who has so suddenly stepped into notoriety and wealth, cast, of course, a strong suspicion *a priori* upon the real value of the discovery. This suspicion is greatly strengthened by the objections from a scientific view which suggest themselves, one of the most obvious being that one attack of the disease does not, as in the case of smallpox, confer any immunity against a second. The effect of inoculation, then, even supposing it to be accomplished, would be, as has been suggested, like that of vaccination against bronchitis. Dr. Gibier examined the blood of persons who had been inoculated, but was unable to detect the presence of microbes in it during twelve hours succeeding the operation. As to the identity of the epidemic now so extensive and fatal in Spain with Asiatic cholera, there is no question in the minds of the French Commissioners, nor of any one else; nor, unfortunately, is there any doubt as to the wretched sanitary and hospital arrangements which exist to meet it.

In the hospital wards the patients lie on dirty beds, too often surrounded with filth and covered with vermin, while swarms of great black flies are allowed free access through the windows unprotected by netting. There is not a hospital that Dr. Gibier visited in Spain in which all the rules of hygiene and comfort are not grossly violated. It is impossible to obtain any reliable statistics concerning the epidemic, for the simple reason that the number of deaths reported by the local authorities are, in many cases, wilfully perverted, and the census of the population is worthless. The alcalde of one village visited had just been fined by the colonel in command of the *cordon sanitaire*, which surrounds the province of Valencia, for reporting two deaths in a day when there had been several fatal cases in the village. An incident characteristic of Spain attended the departure of the commissioners from the infected district. They were forced to leave the train and stand around without shelter for two hours after dark on a cold, rainy night, while the railroad

employees were at work disinfecting the cars. This entirely useless proceeding consists in burning pans of sulphur in each compartment. Dr. Gibier had left a lot of loosely corked vials containing a choice collection of cholera microbes in the rack of his compartment. "My microbes," said he, "were as alive and lively after the disinfecting process as they were before it occurred."

The report of the French Commissioners has been made public and confirms in the main the above statements. It moreover confirms the view we have taken from the first of this alleged discovery. We are not surprised that the report should discredit Dr. Ferrán's pretensions; but his unsatisfactory treatment of the French Commissioners—apart from the entirely inadequate apparatus used for his researches—is the strongest proof that the Spaniard's methods will not bear the light of scientific investigation.

The appointment of a committee of inquiry by the French Academy of Medicine was the only thing which had given an air of seriousness to Dr. Ferrán's proceedings, and we have suspected from the first that the appointment of such a committee was largely due to his extravagant adulation of Pasteur and the French methods of bacteriological research. That such a committee should be allowed to depart, or rather be sent back, with the feeling that it had come on a fool's errand, is almost enough of itself to prevent any further serious consideration of this humbug, and we hope to hear but little more of the *peronospora Ferráni*.

#### THE DEATH OF GENERAL GRANT.

SOME time ago we spoke of the patient endurance of the great General who has just passed away, and expressed our admiration of the calmness with which he awaited the result of his painful malady. Probably no man ever had a greater pressure brought upon him to abandon the certain and the known and trust to specious promises, but with the strong commonsense that was a marked characteristic of his whole life, he accepted the truth and awaited the end with a patience that has endeared him to the nation.

The amelioration of his symptoms was the signal for an attack upon the diagnosis of his physicians which illustrated only too clearly the attitude of the laity are ever ready to take in regard to a medical opinion not in accord with their wishes. Undoubtedly the cry of ignorance and narrow-mindedness which was so loudly raised was not shared by the thinking few, but Grant himself seems to have appreciated the fact that the diagnosis had been carefully made and had not been arrived at without due consideration of other hypotheses, and that all the resources of modern surgery and all the certain knowledge concerning his malady were already at

his service. He seemed to appreciate the fact that the profession, whose duty and pride it was to save his life, were quite as trustworthy as the men of lofty pretensions and pleasant promises. We trust his example will not be lost to the world and that others may learn from him that truth does not become untrue simply because it is unpleasant.

### MEDICAL NOTES.

—The aesthetics of the sickroom have received an impulse from Dr. Lawson Tait, who is said not to accept homely women as nurses for his patients. If Dr. Tait's specialty were concerned with the male sex, the wisdom of his selection would be even more apparent. Mrs. Stowe makes one of her shrewd (male) characters say that a pretty face in the singers' seats is a means of grace, and the same philosophy seems to be applicable to what is under the nurse's cap.

BOSTON.

—A number of importers of rags in Boston have, it is said, signed a petition setting forth their objection to the action of the Boston Health Board in refusing in certain cases to accept the certificate of consuls in foreign ports as to the immunity of those localities from cholera, and in insisting, in cases where not satisfied with the thoroughness of disinfection said to have been made in foreign ports, upon a second disinfection by their own agents here before allowing the cargo to land. The local board, however, persists in its precautions, having found abundant evidence as to the unreliability of some of the consular certificates and the inefficiency of the disinfection (by burning sulphur alone) practised in most of the rag-exporting ports.

—There seems to be something in the position of pension examiner in Massachusetts not attractive to the better class of medical men. The unsavory matters which have occupied the courts of late in regard to a former member of the board are fresh in our readers' minds. The changes in the *personnel* of the board have lately been quite numerous, and no less than three gentlemen have resigned because of unwillingness to serve on a board constituted in accordance with the wishes of Commissioner Black, who retains upon the board a physician with whom others apparently cannot serve. The charges against this gentleman should be investigated and either he or they be withdrawn. We understand that the methods of transacting business are such that any one of the examiners might easily compromise his two associates. It is a pity that the government should allow even a shadow of a suspicion to fall upon its relations to the old soldiers.

—The following Boston gentlemen have received the honorary diploma of La Société d'Hygiène : Drs.

H. P. Walcott, late of the State Board of Health; Charles F. Folsom, formerly health-officer of the State Board of Health; Samuel W. Abbott, of the State Board of Health, and Prof. E. S. Wood, of the Harvard Medical School.

—The force of the public prejudice against medical students, as shown by the readiness with which any horrible deed whose motive is not evident is set down by a portion of the public press as the prank of some graceless medical student, is illustrated by the theory advanced in the case of the murdered woman whose mutilated body was found last week in two potato sacks in Charles River and Boston Harbor, that it was done by some medical student thirsty for gore and a sensation. The facts that the medical schools were all closed, that dissecting material is at a premium (which would effectually prevent the impecunious student from squandering it so recklessly), the absence of any mark of the scalpel and the presence of those of an axe,—all failed to convince some minds until the results of the autopsy were made known.

### Miscellany.

#### COMMENTS IN THE MATTER OF THE INTERNATIONAL CONGRESS.

The hot weather does not modify the acerbity of the discussions in most of the journals of this country in the disputed matters relating to the Congress. But no progress appears to be made toward a solution of the difficulties. In addition to the withdrawals already chronicled in our columns of the entire committee appointed from Boston, of those from Philadelphia and other cities, the same action has been taken by the Baltimore members, twelve in number, and also by the Washington members. Resignations, moreover, are reported from St. Louis and other Western cities.

*The News* remarks: "The leaders of the new committee are at present actively engaged in trying to devise some form of compromise which will enable them to retain their own positions, and at the same time prevent further defection, but this cannot be done. The leading members of the profession of the principal cities of the Union have declared their determination not to accept office. The presidents of nine of the Sections, the Secretary-General, as well as a large proportion of the Vice-presidents and members of the Councils, have likewise declined to cooperate under the new organization. Self-respect, if nothing else, demands that a committee which has been so thoroughly discredited by the profession at large, and whose inability to organize an International Congress has been completely demonstrated, should at once resign. If its members do not, they fully justify the charge which has been freely made—that they place then individual interests above those of the profession, and that they prefer to see the Congress destroyed than themselves without office."

It adds, moreover: "The men who are engaged in original research, and who are best known as

those who are contributing to the honor and dignity of American medicine by their writings and teachings, are not usually active in medical politics or in the supervision of their medical brethren, nor are they given to log-rolling and striving for office. For the past ten years these men have been becoming dissatisfied with the tone of the American Medical Association, and while many of them have not formally severed their connection with it, they have nevertheless ceased to attend its meetings. Many of them give their entire interest and work to purely scientific associations such as the College of Physicians and the Academy of Medicine, to pathological societies, or to societies devoted to specialties, in which the scientific physician is not liable to be annoyed and overborne by wire-pulling and loud-voiced demagogues. The result of this interference with the Congress, and of the evident determination of the leading spirits in this movement to maintain their control over the Association, will be to alienate still further the scientific workers and teachers of the profession, and already we hear rumors of the formation of a new National Society, to meet the wants and wishes of this class. This result will fatally damage the influence of the Association, and it is greatly to be regretted, for the Association has done good, and might do much more if it were conducted in the interests of the whole profession."

The organ of the American Medical Association, after complaining somewhat bitterly of the *puerility* of the committees in Boston, Philadelphia, and Baltimore, concludes (July 18th): "We understand the officers of the committee are already taking the preliminary steps for another meeting early in September; and if the professed friends of the Congress will take half as much pains to aid the committee in completing wise and satisfactory arrangements as some of them do to find fault and throw obstacles in the way, there will be no trouble in securing good arrangements and a successful Congress."

The same journal, in its issue of July 25th, says: "Such is the exact position of a handful of very respectable members of our profession in four cities, who committed the two radical mistakes of supposing they could use the American Medical Association alternately as a *decoy duck* or *football* at their pleasure; and that in themselves and a few friends were concentrated all the science and representative capacity of the medical profession of the United States." In view of their present position they might with great propriety adopt the prayer of Scotland's favorite bard:

"O wad some power the gittie gie us  
To see oursel', as others see us!  
It wad frae monie a blunder free us,  
An' foolish notion."

"That we do not err in representing them as a handful or limited number, is proved by the letter of our special correspondent in Philadelphia, on a subsequent page of this number of the JOURNAL. The writer of that letter is one of the most eminent and widely known teachers in the profession of Philadelphia, and his letter will be read with much interest."

Meanwhile, the real friends of the International Medical Congress may rest assured that the Ameri-

can Medical Association, through its present able and judicious Committee of Arrangements, will fulfil all the obligations it incurred, in extending the invitation at Copenhagen, in the most liberal and enlightened manner."

The *Record* is much more hopeless of a successful issue to the Congress. It says: "At present the best hopes for the future of the Congress lie in the fact that we have two years yet before its meeting. This is time enough for a good deal of hot feeling to subside and for concessions and compromises to be made. There has never yet been a Congress, we believe, without considerable heart-burning. Any hopes in the emollient effect of time, however, need not be cherished unless with them there is seen a prospect of some very radical changes in the *personnel* of the Executive Committee and the removal entirely of any medico-political issue from the organization and membership of the Congress. A meeting of the American Medical Association, entirely revoking its New Orleans work and restoring the old committee with its liberal policy, might, perhaps, save the Congress. We see at present no other way."

The *London Medical Times* (July 18th), in a long editorial on this subject, says: "We do not wish, and we hope no one on this side the Atlantic will attempt, to revive the memories of the celebrated dispute on the Codes. We believe that the late Dr. Panum, the lamented President of the Copenhagen Congress, distinctly insisted, when the invitation to America was accepted, that the code question should not be raised; and we feel sure that a very large majority of English and Continental practitioners will refuse to cross the water if this understanding is not rigidly kept to. They will feel, too, that if they go to Washington they can only go as the guests of an undivided profession. A Congress from which the most distinguished representatives of American medicine were excluded or had withdrawn would not be worth going to as a scientific meeting, while the remembrance of the bitterness and heartburnings which had attended its organization would rob its social distractions of all their charm. It would be like feasting with a man, while his wife, unjustly divorced, stood in the street watching. We can assure our American readers that in the present case the best English sympathies will be with the wife. The men whom English visitors, if they go, will go to see and hear are the very men who have been elbowed out of the Congress. The scientific success of a Congress does not depend on numbers, but on quality. The profession in America is no doubt rich in numbers, as well as in scientific activity, but it is not so rich that it can afford to play all Europe with only pawns on its side of the board."

## Correspondence.

### COPPER AND CHOLERA.

DORCHESTER, Mass., July 22, 1885.  
Mr. Editor, I desire to call attention to a paragraph which is seen in both professional and secular papers from time to time, and which is probably erroneous.

It is to the effect that copper is a protection against cholera, and that the workmen employed in copper-works are entirely exempt from epidemics of this description. The error consists in attributing to copper the virtue that belongs to sulphurous-acid gas, a substance nearly always present where copper ores are worked, the copper being combined with sulphur, which passes off as sulphurous-acid gas during the process of obtaining the metal. A similar immunity has been found in all works where this gas is produced—as in the manufacture of ultramarine, in lead-smelting works, etc.

In 1871 or 1872 (I forget which) the horse epizootic appeared throughout Colorado, attacking almost every horse and mule in the country. I was running smelting-works at the time, and employing some twenty animals of this description, all of which escaped, except some half-dozen mules that were employed in hauling charcoal, and were most of the time at a considerable distance from the furnaces. Yours truly,

E. D. PETERS, M.D., M.E.

### OVERCROWDING AT DANVERS LUNATIC HOSPITAL.

DANVERS, MASS., July 20, 1885.

*Mr. Editor.*—Will you kindly allow me a little space to make a statement to physicians, concerning the present condition of the Danvers Lunatic Hospital,

which may influence some who think of sending patients here. For a long time the hospital has been so crowded as seriously to interfere with the comfort and welfare of the patients, and this has now reached such an extreme degree that nearly 200 of them are obliged to sleep upon beds placed on the floors of the corridors. The Legislature having adjourned without making any provision for the increased number of the insane, I do not think any adequate relief from this evil is probable in the near future, and I desire to say that it is impossible for me to give what I consider proper care and treatment to patients who are not quiet and orderly. This is especially true of those who have been accustomed to comfortable surroundings at home, as I am often forced to give them uncomfortable and almost indecent accommodations among exceedingly disagreeable associates. I regret the necessity of this statement, but do not wish physicians or friends to send patients here under a misapprehension as to the actual conditions.

I also wish particularly to urge that feeble chronic cases, which simply need nursing, be retained in their homes, or in local hospitals, as there are no facilities here for treating more of that class and they occupy room needed for patients who cannot be properly treated except in a hospital for the insane, and I shall be obliged to return them, as the trustees of this hospital have recently instructed me to have patients of this class removed to the town where they have settlements, as authorized by law when the hospital is overcrowded.

WM. B. GOLDSMITH, M.D.,

*Physician and Superintendent.*

Deaths reported 3,112: under five years of age 1,738; principal infectious diseases (smallpox, measles, diphtheria and croup, erysipelas, fevers, and diarrheal diseases) 1,222, consumption 271, lung diseases 155, diarrheal diseases 391, diphtheria and croup 85, measles 31, scarlet fever 31, whooping-cough 20, malarial fevers 15, typhoid fever 16, cerebro-spinal meningitis 13, erysipelas 10, puerperal fever seven, smallpox one. From scarlet fever, Philadelphia 10, New York nine, Brooklyn seven, Boston and Lawrence two each, Waltham one. From whooping-cough, New York nine, Philadelphia four, Brooklyn and District of Columbia two each, Boston, Baltimore, and Cambridge one each. From malarial fever, New York eight, Brooklyn and Baltimore three each, District of Columbia two, Philadelphia one. From typhoid fever, Philadelphia six, District of Columbia three, Brooklyn and Boston two each, New York, Holyoke, and Salem one each. From cerebro-spinal meningitis, Fall River four, New York three, Buffalo and Nashville two each, Holyoke and Taunton one each. From erysipelas, New York three, Philadelphia and Baltimore two each, Brooklyn, Providence, and Cambridge one each. From puer-

peral fever, New York, Brooklyn, and District of Columbia two each, Providence one. From smallpox, New York one.

Cases reported in Boston: diphtheria 33, scarlet fever 27, measles 26, and typhoid fever 17.

In 112 cities and towns of Massachusetts, with an estimated population of 1,371,812 (estimated population of the State 1,955,101), the total death-rate for the week was 23.81 against 17.33 and 13.48 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending July 11th the death-rate was 18.3. Deaths reported 3,126; infants under one year of age 812; acute diseases of the respiratory organs (London) —, diarrhoea 161, measles 141, whooping-cough 104, fever 32, scarlet fever 20, diphtheria 19, smallpox (London 11, Bristol, Hull, and Sunderland one each) 14. The death-rates ranged from 12.2 in Derby to 25.8 Manchester; Birkenhead 15.7; Birmingham 16.7; Blackburn 18.1; Bradford 15.3; Hull 15.7; Leeds 15.3; Leicester 16.1; Liverpool 21.4; London 18.0; Nottingham 15.8; Sheffield 18.8; Sunderland 21.6. In Edinburgh 15.6; Dublin 22.6; Glasgow 20.8.

The meteorological record for the week ending July 18th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

## INTRODUCTION TO A DISCUSSION ON THE DIAGNOSIS AND TREATMENT OF TUMORS OF THE BLADDER, AT THE BRITISH MEDICAL ASSOCIATION ANNUAL MEETING, 1885.

BY REGINALD HARRISON, F.R.C.S.

*Surgeon to the Liverpool Royal Infirmary and Lecturer on Clinical Surgery in the Liverpool University.*

MR. PRESIDENT AND GENTLEMEN:—

At the request of the Secretaries of this section, I have undertaken the responsibility of opening a discussion on the diagnosis and treatment of tumors of the bladder.

Only a few years ago, any one occupying this position would probably have felt bound to offer an apology to his audience for the scantiness of the material upon which he had to dilate; such, however, has been the progress of surgery within our recollection, that I feel myself differently circumstanced, and shall ask your indulgence in my attempt to compress the large amount of material which the experience of many has already supplied.

Time is more than precious on occasions such as these, and I must, therefore, avoid all historical references, deeply interesting and instructive as they are, and deal with my subject from a purely clinical point, feeling assured that this is the direction which will best answer our purpose to-day.

Under the guidance of the distinguished surgeon who presides over our section, and in the presence of many who have made valuable contributions to this subject, I have the satisfaction of anticipating that the speakers who follow me will fill in the numerous gaps I must necessarily leave, and correct defects in my statement of which I am only too conscious.

I shall confine my remarks to tumors of the bladder proper, adopting where requisite the nomenclature set forth in the report of the Committee appointed by this Association, for the drawing up of which we are largely indebted to Mr. Paul.<sup>1</sup>

It is hardly necessary that I should occupy time with any remarks on the diagnosis of these growths other than those which will incidentally occur. Chief reliance will be placed on the circumstances under which blood appears in the urine, the manner in which the mechanism of micturition is interfered with, the presence or absence of evidences of new growth in the excretion, and the direct and indirect indications which may be afforded by the use of the sound or the catheter.

It will be convenient to arrange tumors of the bladder into two classes or stages; (1), those which during their entire existence, or for a portion of it, occasion either slight or no distinct indications of their presence, and (2), those which declare themselves by symptoms either seriously disturbing the function of micturition, or which by their constancy or degree threaten the life of the patient.

From the manner in which I have thus attempted in general terms to make use of a classification, it will be at once understood that individually I should be guided as to treatment, not by the fact alone that a patient has a growth in his bladder, but by the symptoms it produces.

The more subjective evidence that a person has a tumor of this kind would not, I submit, warrant the

adoption of any operative measures to effect its removal, even if in addition it were possible to demonstrate its existence by other means than digital exploration. Some tumors of the bladder which have been found in the *post-mortem* room appear to have had no history connected with them, and instances are known in patients of the total disappearance, after varying intervals, of symptoms which were unmistakably those of villous growth or papilloma. Of the latter I believe that I am acquainted with more than one case. These are important facts, as they seem to indicate that what nature can accomplish art may hope to imitate. How these growths thus disappear, whether it is by an accidental self-strangulation, or by an inflammatory act, it is impossible to say; but that they do so occasionally, without recurrence, I have not the least doubt.

Unfortunately, however, by far the larger proportion of them sooner or later pass out of the condition where operative interference is not to be recommended, and enter upon what I have taken as the second stage of their existence. Whether the transition is slow or rapid, gradual or sudden, much depends on their kind; but whether innocent or malignant, primary or secondary, the great majority of them, sooner or later, make it apparent that life will eventually be destroyed, either by persistent hemorrhage, or by the degree micturition is interfered with.

The question of operative interference will now be entertained, but before anything further can be said as to the hope of success which is likely to follow this, it is necessary that a more accurate knowledge of the connections of the growth should be obtained. This brings me to speak of digital exploration of the bladder.

If you will look at the two drawings which I show, you will see examples of two very opposite conditions; one where everything may be hoped for from operation, where complete recovery modern surgery has proved to be possible; and the other where nothing is to be expected except the relief of those symptoms of urgency which have rendered an opening into the bladder necessary. The first drawing represents a villous growth of three and a half years' duration, with a narrow pedicle, and is taken from Quain's *Clinical Lectures*, (Plate XXIV), which have recently been published; the second is an epithelioma extensively connected with the posterior wall of the bladder, from a specimen of my own in the Liverpool Museum.

Illustrations like the latter tend to show that though the diagnosis may be correct, the prognosis, so far as operative treatment is concerned, may fall very short of our desire, as the propriety of attempting to remove such growths can never be foretold until the finger has been placed in contact with them.

Digital exploration of the bladder relative to the treatment of tumors seems to me to be called for when it can fulfil at least three objects: (1) the relief of symptoms which are otherwise irremediable; (2) for verifying the diagnosis of tumor; (3) for determining whether the removal of the growth can be proceeded with. The circumstances which require a surgeon to open the bladder for the purpose of finding out what is inside it must be very exceptional, but when by this proceeding the three important objects I have mentioned are to be obtained with little risk, then its importance cannot well be overrated. There are recorded cases which seem to suggest that if the

<sup>1</sup> British Medical Journal, January 17, 1881.

exploratory examination had been limited to providing a means for draining the bladder, and for examining the growth, it would have been better.

In the case of an epithelioma of the bladder, such as you see in the illustration, which I have also taken from Quain (Plate XXIX), to attempt its extirpation is obviously out of the question; to explore it with the finger, and to feel so far satisfied, and, at the same time, to give the patient an opportunity of emptying his bladder completely by means of a short and open road so long as he lives, is legitimate; nay, further, experience has already sufficiently shown that there is no better way of controlling the considerable bleeding which nearly always attends these cases than by providing the means of permanently maintaining the bladder in a condition of more or less contraction.

And now a few words in reference to the operation for exploring the bladder with the finger. If there are two ways to a place of about the same length but with somewhat different surroundings you may depend upon it you will have two sets of travellers, with the same aims, but with very opposite notions as to the respective merits of the two routes—so with the bladder; though we are agreed as to the necessity of exploring it, we are not so unanimous about the route. In this country, as well as in America, median perineal urethrotomy seems to be preferred; whilst in France, the clauus of the supra-public operation have been forcibly urged by Professor Guyon, Ponsson, and others. Sir Henry Thompson has advocated the former method, not only as being the safest and most convenient for exploration, but, as he has shown by examples, for extirpating these growths. It seems to me that this form of procedure is to be preferred on several grounds.

In the first place, it provides a direct access to the more usual position of these growths; by a continuance of the incision forwards into the membranous urethra and backwards into the extreme limit of the prostate, it affords more room for the manipulation than at first sight appears; but what is of more importance, it is, I believe, the best position for the drainage to follow, which is a most important item in the management of these cases. If a perineal exploration shows the position or character of the tumor to be such as would be benefited by an access from the front, should it be determined to remove it, there is nothing to prevent the addition of the supra-public incision, as Billroth demonstrated. A supra-public incision is none the worse for having a more dependent opening, as Frère Côme practised a hundred years ago in connection with his success as an operator for stone. But, as I have already intimated, the great importance of the after-treatment, in relation to thorough drainage, renders to my mind the perineal procedure almost a necessity.

In connection with this point, it must not be forgotten what are the conditions under which these operations are often undertaken. In addition to the tumor which it is proposed to remove, there are usually present, either in the bladder itself, or in the organs associated with it, pathological changes which add considerably to the danger arising from the retention of anything which ought to escape. The viscous is occasionally accumulated, the ureters are patent and frequently largely distended, whilst the kidneys are rarely sound where the obstruction caused by the growths has been of long continuance. Hence we have much to fear from any extension of a suppurative process

after the operation, as I have seen in two instances which have recently come under notice. One of the best safeguards against a contingency such as this is a thorough drainage, and this I think can best be secured through an opening in the perineum.

The feasibility of attempting to remove the tumor having been determined by digital exploration, the precise means of doing so has now to be considered.

It will not be necessary for me to describe at length how this has been affected after an opening has first been made into the bladder; in some instances the finger-nail has sufficed; in others, various kinds of forceps; quite recently, Mr. Pitts has recorded<sup>1</sup> a case where a growth was successfully removed by the *écraseur*. In examining two cases which terminated fatally, it appeared that if it had been possible to have applied a ligature round the pedicles, and then to have removed the growths cleanly, either with forceps or scissors, a different result might have followed. The nearest approach to such a proceeding seems to be one recorded by Mr. Henry Morris,<sup>2</sup> who, failing on the first attempt to remove a growth in consequence of the want of the most appropriate means for extraction, the patient was left for two days, when the tumor was found prolapsed into a wound. Having stretched the edges of the wound apart by retractors, he succeeded in placing a ligature of catgut over the base of the growth and removing it with scissors. The patient made a good recovery.

When, after the bladder has been opened and explored, it seems practicable to remove the tumor, this should be effected as completely as possible; to take away a portion of it is to leave the remainder to inflame, suppurate, and possibly to become gangrenous, thus providing a fruitful cause for pyelitis, through the largely dilated ureters. Not being entirely satisfied with the forceps that hitherto have been used for the purpose of seizing and extracting these growths, I have had some others made for me by Messrs. Krohne & Seemann, which, so far as I have been able to judge of them in practice, are well adapted for this object.

It will be seen that they consist of an ordinary pair of bladder-forceps, with a free margin; by this contrivance it is almost impossible to do any damage to the wall of the bladder itself. The removal of the growth is effected partly by twisting slowly with the hand, and partly by the crushing action of the jaws of the instrument. In the exploration of the pedicle, both before and after the removal of the growth, I have found one of Marion Sim's enucleator hooks exceed-

<sup>1</sup> *Medical Society*, May, 1885.

<sup>2</sup> *The Lancet*, April 24, 1885.

ingly useful. If, however, the connections of the tumor are extensive, and there is a doubt as to whether all can be got away without doing serious damage to the bladder itself, I feel sure that we had better content ourselves with the opening, which may under all circumstances be safely made, and the drainage that this opening with a suitable apparatus will provide. The lesser proceeding has in many instances proved the means of arresting hemorrhage, and of adding materially to the comfort, as well as to the life, of the patient, even where it has been found impossible either to remove the tumor or with safety to reduce its size.

Of excision of portions of the male bladder I have had no experience; so far as I am aware it has been limited to some experiments on the lower animals, in furtherance of the subject which we have now under discussion.

In conclusion, it cannot be denied that operative surgery has already proved itself to be of considerable service in the treatment of a very distressing class of disorders, and for which little is to be hoped for from medicinal agencies.

If I may be thought to have been too general in some of my remarks, permit me to say that this has been my intention; my object has been to open a discussion, and not to narrow it unnecessarily. The time has not arrived when it would be possible to lay down hard and fast lines of demarcation: much must be left to individual judgment. Where therapeutics are to end and surgery is to commence, experience and the application of those principles which are of general utility, and are not the exclusive property of any one set of organs, will enable us to determine what is best for each case as it presents itself to our notice.

Time will not permit me to illustrate these remarks with cases from my own practice, where I have operated in accordance with the views expressed in this paper; these have already been noticed in a previous communication.<sup>1</sup>

I hope that Dr. Stein, of New York, who has contributed importantly to the literature of this subject,<sup>2</sup> can tell us something to-day as to the general results following operative treatment, drawn from his most recent investigations upon this point.<sup>3</sup>

And what applies to the male is equally applicable to the female, though with the latter, by reason of the anatomical differences in the parts, both exploration and removal can be more readily affected. My friend, Dr. Alexander, of Liverpool, was, I believe, one of the first in this country to demonstrate the successful removal of growths from the bladder under these circumstances.

♦

#### SOME OF THE MENTAL ASPECTS OF NERVOUS DISEASE.<sup>1</sup>

BY HENRY R. SEDGWICK, M.D., OF BOSTON.

THE object of this paper is, in general, to direct attention to the relationship between physical and mental disease (to make a distinction of terms more convenient than sound), but more particularly to

demonstrate the close affinity existing between the nervous and mental forms of disease. For this purpose I have grouped together several of the prominent nervous affections, giving the chief mental manifestations which are found associated with the different forms. I have also pointed out how these mental phenomena differ essentially according as the disease is structural or functional (i. e., due to discovered anatomical lesion or not), and have touched upon some of the pathological and clinical relations of individual nervous disorders to mental change. By this means I hope to suggest a more comprehensive idea of nervous disease than is prevalent. As I have merely attempted to prompt inquiry in the direction indicated by touching upon prominent points of practical and general interest, and as time will not allow more than a superficial treatment of a subject so extended, its consideration is confessedly incomplete.

A distinguishing feature of the numerous nomenclatures of insanity which have been proposed during the last twenty years, has been the tendency to classify mental diseases according to the various bodily disorders or physiological states which have been believed to be the most potent factors in their causation. This has shown increased recognition of the fact, that in the interdependence of the various parts of the organism in disease, development and decay, the cerebral changes underlying insanity play a prominent part.

While it must be admitted that a classification of this kind—by causes—is far from trustworthy as a system of grouping the essential characters of disease, it certainly helps to stimulate inquiry as to the association of mental and bodily disorders, and by thus taking insanity from its isolation as an independent affection, its importance in medicine becomes more generally recognized, and consequently far greater clinical interest is excited. Phthisis pulmonalis, syphilis, rheumatism, cardiac disease, even diabetes are some of the diseases of the body proper which are known to be not infrequently expressed in part by psychical disturbance, amounting in some cases to actual insanity. Indeed, so extended has become the field of observation through the vast accumulation of recorded facts in this direction alone, not to mention those pertaining to nervous diseases in their relation to insanity, that it has truly been said of mental medicine that its axis has become displaced, and that it no longer revolves around psychology.

Disorders of the nervous system are obviously the most nearly allied to insanity of all other portions of the organism. Taking up first the structural diseases of the brain and cord, we find that in the majority of cases some mental impairment is usually present, although it is so slight as to escape the unpractised eye until the destruction or inflammatory process has become extensive. The mental symptoms attending such lesions show a loss rather than a perversion of mental activity.

The absence of insanity from the clinical history of most cases of tumor of the brain, cerebral abscess, etc., is often instanced, but mental change is not so infrequent in this connection as is usually supposed. In an analysis of two hundred and sixty-four collected cases of this kind in the "Dictionnaire Encyclopédique des Sciences Médicales," although but six are complicated with actual insanity, eighty-five show intellectual disturbance of some kind.

Cerebral apoplexy shows the connection between

<sup>1</sup> On the Surgical Treatment of Hematuria, Liverpool, Medical Chirurgical Journal, July, 1881.

<sup>2</sup> A Study of the Tumors of the Bladder. New York, 1881.

<sup>3</sup> Results of Operations on Bladder Tumors, New York Medical Record, No. XXVII, 1885.

<sup>4</sup> Read before the Massachusetts Medical Society, June 9, 1885, and recommended for publication by the Society.

the mind and the brain, in that it frequently has a sequel of mental impairment. This may be nothing more than unusual lequacity, emotional instability, slight lapses of memory, irritability, want of readiness in expressing thoughts, but careful observation will disclose a change. In those rarer cases in which the disturbance exceeds moderate bounds and becomes what is known as paralytic insanity or organic dementia (in which category come also mental disturbances following softening, tumors, atrophies and chronic degenerations of the brain), the mental symptoms are chiefly those of marked enfeeblement, viz.: decided loss of memory, frequent crying spells without cause, inability to understand what is said, inattention to calls of nature, together with more or less helplessness. Excitement, violence and destructiveness due to hallucinations and delusions, less frequently appear and make asylum care necessary.

Now, the value of a due observance of the mental symptoms following cerebral apoplexies lies in the possibility of assisting the process of repair by measures directed toward mental rest. Visits of solicitous friends soon after an attack or the premature return of the patient to business are surely to be avoided in the light of the above possibilities. At all events it is certainly wise for the physician to inculcate extra consideration on the part of the family toward a patient in these circumstances, even when he has recovered from the immediate effects of the "stroke." If by the employment of electricity we seek to hasten the use of the hemiplegic limb, should we not endeavor at the same time, by a judicious regulation of the patient's immediate surroundings, to meet the requirements of his altered mental state, and to secure to the patient by so doing a more prompt and permanent return of mental capacity and vigor? In other words, is it wise in such diseases to attend solely to motor symptoms, and to allow the mental condition to take care of itself?

*Cerebral Syphilis.*—The facts concerning the relation of cerebral syphilis to insanity which have the most support are those which find in it the cause of a large number of cases of general paralysis. This disease is thought to be frequently dependent on syphilitic disease, and there is better evidence to support this view than that which traces a connection between it and insanity of any other form. Still, some of the best authorities acknowledge that they cannot distinguish between syphilitic general paralysis and non-syphilitic general paralysis, except by the history of infection; the symptoms, course and pathological changes being the same, and anti-syphilitic treatment often failing to have any effect whatever.

The connection between cerebral syphilis and ordinary non-parietic insanity is still more difficult to trace. Dr. Sankey, one of the foremost English alienists, observes that when mental disease arises in one with syphilitic taint, it obeys the same laws in its evolution as other cases. The mental disease may be either ordinary insanity or general paralysis, and perhaps more frequently the latter. Dr. Hughlings Jackson says, "The syphilitic affections of the nervous system are very indirectly of nervous origin. Such names as syphilitic epilepsy, syphilitic insanity, though convenient, are not scientifically accurate terms. There is nothing in any kind of nervous symptom which enables us to diagnose syphilitic disease of the nervous system. The pathological processes by which syphilis

causes nervous symptoms simply imitate non-syphilitic morbid processes."

These facts are cited to be set against a not uncommon tendency to suppose all insanity syphilitic which occurs in syphilitic subjects, and to suggest a guarded opinion as to such a cause in the light of the preceding observations, not to speak of the extreme rarity of cerebral syphilis, and the comparative infrequency of insanity caused even indirectly by syphilis.

*Locomotor Ataxia or Tabes Spinalis.*—This, the most prominent structural affection of the spinal cord, has mental complications of various kinds. In the first place, mental enfeeblement, slight change in disposition, general sadness, loss of interest in family and business, emotional changes, and perhaps suicidal ideas, are known to be not uncommon in the initial stage of this disease; and we generally find the mental faculties weakened toward the end. But these symptoms do not amount to actual insanity.

The relation of general paralysis of the insane to true locomotor ataxia is an intimate one, and due, it is thought, to an actual propagation to the brain of the changes of the cord. The cases of this kind which I have seen in asylums had been transferred from general hospitals, and manifested extreme loss of mental power with convulsive seizures and imperfect articulation, symptoms which had supervened during the last stages of tabes. They certainly bore a striking resemblance to cases of advanced general paralysis of the insane. Numerous cases of this sort are recorded. It is true that the sclerosis of the posterior columns of the cord does not, as a rule, extend beyond the bulb; but according to Althaus, although there may be no change whatever in the brain in cases of tabes, when that disease ultimately becomes complicated with epilepsy, general paralysis of the insane and other analogous conditions, diffuse changes of the cortex and the pia mater of the brain have been discovered.

Again, cases are recorded by Savage, in which typical locomotor ataxia preceded; in which it developed with; and, finally, cases in which it appeared throughout the course of, general paralysis.

There is still another class of cases of tabes associated with ordinary non-parietic insanity. These usually take the form of melancholia, with delusions of persecution and various hallucinations, depending probably on lesions of the optic, auditory or other sensory nerves.

*Disseminated Spinal Sclerosis.*—It is not generally known that besides the dementia or general weakening of the mental faculties commonly supervening in the latter stages of this disorder and of paralysis agitans, these diseases may also be a cause of other forms of insanity, and it has been believed, in the same manner as locomotor ataxia, viz.: by extension of the morbid process from the cord to the brain. This is, however, somewhat a matter of conjecture; at all events, true insanity is occasionally met with in patients suffering from disseminated sclerosis and paralysis agitans. It may present itself in various forms, but mental depression is the most prominent feature. The brain lesions, considered by some authorities to be the origin of this mental disturbance in disseminated spinal sclerosis, are isolated patches of diseased tissue, springing from the same cause as the chief disorder in the cord.

Enough has now been said to show that mental complication in structural disease of the nervous system is a somewhat frequent occurrence, and that it

usually takes the form of dementia or a loss of mental power, limited function in other words, resulting from organic change with incomplete repair.

*Functional nervous disorders*, i. e., the convulsive and other neuroses without discovered anatomical lesions, are, as will be shown, far more often accompanied by mental symptoms than are the structural nervous affections. Moreover when the mental phenomena of this kind of nervous disorder pass the limits of sanity, they do not follow the same lines as when they are due to coarse lesions. For in the former, instead of mental inaction we find increased but perverted mental activity, and the emotions, the intellect, the will, one or all, may be involved. Witness the delusions of the epileptic, which may follow or precede the convulsions and the instability and impulses of the hysterical patient.

The only exception to this rule is the hebeteude arising from and increasing with repeated attacks of epilepsy. But this is not the immediate manifestation of the disease, which is shown in the convulsions and the mental states directly accompanying them, while, on the other hand, the mental dulness referred to is a final result of the excessive functional disturbance in the brain. It is in fact quite probably based upon minute structural degeneration, as the only lesions which can fairly be called peculiar to epilepsy are certain histological ones, which are thought by competent observers to be the effect of the repeated passive congestion to which the brain has been exposed.

*Epilepsy*.—Of the greater neuroses, epilepsy may be said to lie at the threshold of mental disease, so intimate is its relation to insanity. The different manifestations of this relationship are too well known and too numerous to require more than their mere enumeration. In the first place, the irregularity of the mental state of the non-insane epileptic is noticeable. In many it is a perfectly natural one, but more often the whole disposition is colored by conduct peculiar to the diseased state, and either an unusual irritability or an extreme and obsequious amiability is noticeable. Its remoter alliance to insanity is shown by the fact that many epileptics have insane parents; its close connection by the excitement with delusions or hallucinations which sometimes precede the fit, giving rise to the intellectual aura or oftener following it in various aspects, of which homicidal furor is the most significant one; again, by mental disturbance replacing the convulsions. Its possible mental states comprise mania with or without a continuance of the unconsciousness which is pathognomonic of the fit, melancholia or dementia.

These are the common and best known features of epilepsy in its relation to insanity; but the fact that seizures in no way differing from those of "genuine epilepsy" may and do frequently occur as a symptom of general paralysis of the insane is apt to be overlooked. It is not an uncommon experience with the asylum physician to receive cases of general paralysis which have long passed for epileptics, owing to a more or less accurate resemblance of the "congestive attacks" of general paralysis to the ordinary epileptic convulsions. Moreover, the fact that these attacks frequently occur in the initial stages of general paralysis is a matter which renders an accurate judgment of great importance, owing to the widely different prognosis in the two diseases and the danger to persons and property involved, in stamping an incipient parietic a harmless epileptic.

If, therefore, a patient be found to have had a fit for the first time in mature life, no matter how closely it may resemble that of ordinary epilepsy, one should never neglect to consider the possibility of having to deal with a case of general paralysis of the insane.

*Hysteria*, also, is generally known to be a not uncommon associate of insanity in neuropathic families, the common bond between the two disorders being enfeeblement of the will. A family I have in mind affords a good example of this association, one member being sane, but manifesting an undue emotional instability, impulsiveness, etc., and another actual hysterical mania, while a third developed melancholia with delusions.

This relationship of insanity to hysteria by heredity, by the way, would seem to favor the views recently advanced as to the probable cerebral origin of many cases classed under the heads of spinal concussion, spinal irritation, railway spine, etc., cases now recognized as hysterical, or, as some prefer to style them, cases of functional nervous disorder. For the most experienced observers claim, with Sir James Paget, that in these cases we shall find some evidence either of mental disorder in the previous history of the patient himself, or that he comes of a stock in which mental or emotional disturbances or peculiarities, not necessarily amounting to insanity, have been recognized as prominent in the family record.

The mental phases of ordinary hysteria, viz.: craving attention and sympathy, alternate outbursts of crying or laughter, the spirit of contradiction, of complaint and tendency to duplicity, as well as impulsiveness, extreme and easily excited anger and enthusiasm, are well known. In these states, which also take on redoubled intensity at the menstrual period, and together with hemianesthesia, etc., convulsions, etc., make up the disease as ordinarily manifested: the proportion between the mental and the motor symptoms is subject to considerable variation.

These psychological disturbances lie on this side of the line which separates reason from madness. But when the mental symptoms strongly predominate, insanity may appear in the patient subject to hysteria in several ways. First, as attacks of acute mania with noisiness, excitement, loquacity, refusal of food and sexual and uterine symptoms. These may occur in place of, during or after an hysterical convulsion, and may resemble the delirium of acute disease. Another form of mental aberration may show itself as an exaggeration of the impulsiveness born of a weak will. When their impulses become irresistible, these patients may commit purposeless theft, more rarely suicide, or they may make specious accusations of the foulest crimes against innocent people. Still another form of insanity may be developed from hysteria by delusional ideas attended by hallucinations of sight and hearing growing slowly out of the natural eccentricities of the hysterical character. Again, there are cases in young people closely resembling what is known as moral insanity. In the latter, with a family history of insanity and perhaps a previous attack in the patient, there is a perversion of the moral power, utterly incorrigible conduct and constant unreliability, together with entire absence of delusions, all springing from the same childishness, frivolity and lack of self-control which are characteristic of the hysteric. Such cases are to be excluded, however, by the absence from their history of convulsive and other features, motor and sensory, of the latter disease.

Although, as has been shown, a moderate proportion of patients suffering from hysteria may develop insanity, such a result cannot be considered frequent, and a contrary opinion is likely to lead to mistakes in treatment. Cases not infrequently come under the notice of the alienist in which the early symptoms having been considered as "hysterical," the precautions necessary to be taken where insanity is indicated have been neglected. This has perhaps led to the actual detriment of the patient, harm to the family and needless anxiety and expense. When, therefore, an altered disposition appears somewhat suddenly in a patient in the form of waywardness, emotional changes, apparent shamming, lack of control, and disregard of proprieties, a careful inquiry directed to the possibility of our having to deal with the prodromata of insanity should be made. For although such symptoms are prominent in hysteria, it is inaccurate and possibly harmful in the absence of any history of motor or sensory complications, to consider and treat the disorder as hysteria. We do not always bear in mind, that states of defective inhibition are common to both hysteria and insanity.

*Hypochondriasis.*—Hypochondriacal symptoms are frequent precursors of attacks of melancholia and but seldom of mania. By their occasional prominence among the countless phenomena of hysteria one is sometimes at a loss to know whether he is dealing with that disease or with hypochondriasis, but here the distinction is chiefly one of terms. The disease hypochondriasis, however, is to a great extent a distinct one, its essence being morbid sensations. It may properly be regarded in its relation to insanity as a rudimentary melancholia. While hysteria may be gradually relieved or cured, actual hypochondriasis is seldom greatly benefited. Hysteria again is a disease of the relatively young, while hypochondriasis belongs with advanced years as a rule. Hypochondriasis also is very near to insanity by inheritance far more so than hysteria. It has been classed by Dubois, Fenchersleben, Savage and others as a species of insanity itself, although the usual and best known view is that a distinction should be made between the two conditions, viz., sane hypochondriasis and hypochondriacal melancholia. The former is chiefly confined to absurd fancies by the patient as to various ailments, beliefs which do not influence his conduct, while the latter is characterized by marked depression with actual delusions regarding himself, such as transformation, decay or obstruction, etc., in some organ or organs, all of which are a perpetual source of misery to himself and annoyance to others, and render him greatly out of harmony with his surroundings.

*Chorea.*—I have stated elsewhere<sup>1</sup> the various conditions influencing the amount of mental disturbance which is present to some extent in all cases of chorea, but I cannot forbear repeating a caution which subsequent experience has emphasized:

"Although many of the ordinary cases of chorea are attended at some stage by mental phenomena, the motor symptoms so far predominate as to completely mask them. On the other hand, in the most severe cases the mental disturbance, which is often quite pronounced, being intensified by the energetic character of the movements, is apt to mislead the practitioner, who considers the patient simply insane, and send him to an asylum. Whereas, if the

case had been recognized at the start to be one of chorea he would hesitate to do so. The case just reported is an extreme example of this mistake and more may be found in asylum records."

Within a year following the date of this statement three cases of acute chorea in adults were admitted to the Danvers Lunatic Hospital, under the same circumstances. Should a case of this kind in a patient who could command better facilities at home be committed to an asylum under like circumstances through a mistaken view of his trouble, it might be a serious matter to all concerned.

*Delirium Tremens.*—Some of the relations of delirium tremens to insanity have a practical value to all practitioners, and will bear restating. I refer to the gradual prolongation of the delirium into acute alcoholic insanity, a result not uncommon in neurotic subjects. In such persons a much smaller amount of liquor is known to prove excessive and to produce delirium tremens. Such patients are also more likely to have an attack of mania engrafted on that of the delirium. When a case of delirium tremens does not recover in the usual time, but the patient remains apprehensive, suspicious, and it may be excited, having also pronounced delusions of persecution, etc., it is by no means necessary to send the patient, if a person of means, to an asylum. The attack of mania is usually short and the prognosis almost wholly favorable. Some of these cases of prolonged delirium tremens are also exceedingly like cases of general paralysis of the insane in the first stage. I have a case in mind where the diagnosis was for weeks impossible, although the patient was under close observation in an asylum. Tremor of the facial muscles and the tongue, unequal pupils and impaired articulation were present, together with exaltation, ideas of grandeur, disconnected talk, etc. As a rule, active maniacal symptoms developing from delirium tremens do not eventuate in the pure insanity ordinarily manifested, nor in maniacal cases of this variety is a repetition of the attack probable unless the same cause be present.

Having considered cases of structural and functional nervous disorder in the relations indicated, I pass now to a form of disease which embraces both of the foregoing, viz., *General Paralysis of the Insane*. The claims of this disease to a place among nervous disorders are acknowledged, but their force is not always appreciated. As its mental phenomena embrace all the usual forms of insanity, so also are its motor and sensory symptoms most comprehensive. This is true, not only as regards similarity in the symptoms, but also in the underlying anatomical lesions of individual nervous disorders. One who is at all familiar with this affection needs only to run over the list of nervous diseases to be satisfied of this. In short, a collection of cases of general paralysis may illustrate pathologically and clinically at some stage, almost any of the disorders of the cerebro-spinal system, structural or functional.

That there is a fundamental difference also between insanity proper and general paralysis seems now to be put beyond question by recent investigations by Professors Ball and Regis, extending over a number of years, and based upon the vital statistics of the families of 318 general paralytics. From these it appears that the disease in question is essentially different from ordinary hereditary insanity, in arising simply from an inherited tendency to cerebral congestion or a

<sup>1</sup> See a Case of Chorea, etc. Boston Med. and Surg. Journal, Jan. 5, 1884, p. 10.

predisposition to coarse cerebral disease. Moreover, it is found that general paralysis and ordinary insanity are not two branches of one family, and can never give rise the one to the other.

We can now, therefore, maintain with a great degree of confidence, that children of general paralytics have no predisposition to insanity, although they are particularly liable to organic diseases of the brain,—of childhood for example,—cerebral paralysis, etc. Thus we find that an accurate knowledge of the relationship of general paralysis of the insane to true insanity is of great value to the physician whose advice is asked concerning the marriage of the offspring of such patients.

It will appear, I think, from what has now been said, that a plea for closer consideration of the mental accompaniments of the nervous disorders is justifiable. At the same time I do not overlook the fact that not only are neuroses with serious mental complications few, as compared with the myriad cases of nervous disease without such manifestations, but also that the association may in some instances be one of coincidence, the insanity occurring merely as an inter-current and independent disease. But giving these facts their full value, it is nevertheless certain that annoying and perhaps disastrous mistakes may frequently be avoided by timely inquiry into the mental condition of many cases of nervous disease. Finally, it is probable that the clinical history of nervous disease in many of its forms will never be complete without a full consideration of its mental aspects.

## CREMATION IN ITS SANITARY ASPECTS.<sup>1</sup>

BY JOHN G. MARBLE, M.D., OF WORCESTER.

### THE TORCH VERSUS THE SPADE.

*"Veniens crepti puro consumimur igni."*

WISE sanitation is now universally regarded as essential to the public welfare. The health and safety of the people is believed to depend quite as much upon preventive medicine as upon curative. The subject of this paper is, *par excellence*, one of preventive medicine. Advances in pathology and therapeutics have no more than kept pace during the past ten years with progress in sanitation, equally important and efficacious in the promotion of health and the saving of life.

The proper method of disposal of the dead is, I believe, one of the greatest, if indeed not the greatest sanitary problems of the day.

Mr. Eassie, Hon. Secretary of the Cremation Society of England, to whom I am indebted for many facts relating to this subject, said at a recent sanitary council, "I am in a position to guarantee facts, and having a lively acquaintance with the history of other sanitary reforms, I think it my duty to declare my opinion that the problem what to do with the dead, transcends in importance every other sanitary question."

The limited time at my disposal to-day forbids me to present to you more than a skeleton of this grave subject.

I shall, however, endeavor to demonstrate the

dangers to the living, from the prevalent custom of earth burial, and the hygienic advantages of cremation over the time-honored, but always and everywhere unsafe practice.

It is an unprofitable, as well as an impossible, task to trace back to their origin either cremation or earth burial. Inhumation had certainly not the most honest origin it, as we are told, Cain buried his brother to conceal his crime. It is a disputed point when urn-burial was first adopted even by the Greeks. The Iliad account of the funeral rites of Patroclus and Hector is, I believe, the first mention of incineration in Greek literature. Rome in her earliest history, according to Pliny, practised earth burial, yet at that early period cremation was also a custom, as stated by Ovid. During the Trojan war cremation appears to have been adopted that the remains of dead heroes might be restored to their native land. We are told that Hercules burnt the body of Arginus, because thus only could he return the remains of the son to his sorrowing father.

Homer causes his dying hero, fainting at the approach of death, to say:—

"Ah, leave me not for Grecian dogs to tear!  
The common rites of sepulture bestow  
To soothe a father's and a mother's woe;  
Let their large gifts procure an urn at least  
And Hector's ashes in his country rest."

Neither is it certainly known whether incineration was originally adopted on sanitary grounds, yet it appears probable from the fact that it was generally resorted to after great battles. It is an undisputed fact, however, that in the fourth century, after Christianity became established, cremation fell into disuse, inhumation becoming thereafter the more general custom throughout Europe. Whether this was due to the fact that Christian people desired thus to distinguish themselves from the so-called heathen or pagan nations, as is claimed, or to the absurd idea that burning the body would interfere with its final resurrection, concerns us little at the present day.

The battle of the torch and spade has been waged in earnest in modern times, since the year 1873 when Professor Brunetti, at the International Exposition in Vienna, exhibited his samples of the results of a scientific cremation. Previous to that date, skirmishes had appeared at intervals with more or less influence ever since good old Sir Thomas Browne, more than two hundred years ago, wrote his excellent paper on Hydriophoria or Urn Burial. But during the past ten years an immense number of papers upon the subject have been published in every country of Europe, and more recently in this country. With few exceptions the practice of earth burial has received the condemnation of science, the world over, and in its stead cremation has been everywhere recommended as a safe, rational, and unobjectionable custom, one which would annihilate powerful sources of disease, and greatly promote the public health.

The final disposition of the dead concerns only survivors, and its importance to posterity cannot be over-estimated. When the population was scarce perhaps it mattered less, but with the increasing tendency of people to congregate, the question before us now increases in importance *pari passu* with increase of population.

The question is, what ought to be done with the dead, by reasoning and intelligent men, in the nine-

<sup>1</sup> Read before the Massachusetts Medical Society, June 10, 1887, and recommended for publication by the Society.

teenth century, with their present knowledge of sanitary science. Shall we continue to bury the corpse in the earth, blindly believing that catering to sentiment will protect us from being perhaps fatally poisoned by gases rising through the soil to pollute the air we breathe, or disseminated through it to contaminate the water we drink, or shall we, like reasonable beings, after proper funeral ceremonies over the body of our dearest friend, allow it to be reduced to ashes in an hour, and thus to leave the earth no worse for having died, if possible for having lived, upon it?

From the moment that the heart ceases to beat, and the vital spark leaves an organized living body, as well of man as of the lowest animal, putrefaction begins its slow and loathsome process. It gradually passes through the successive phases of decomposition too horrible to witness or even to describe, except when necessary, until all the constituent elements are set free by a tedious and dangerous process of combustion. This process may last according to the nature of the soil for ten, twenty, or a hundred years. While this change is going on, every particle of matter around the festering body is being saturated and infected with germs of disease and death. In case death was caused by such disease as yellow fever, small-pox, or cholera, these germs are not destroyed by inhumation, as they certainly are by incineration, but are planted as it were, to sprout again with renewed virulence whenever the soil is afterward disturbed.

So long as we live the vital forces of nature are in operation. Immediately after death, however, the retrograde metamorphosis begins, which will surely render the body, perhaps now beautiful in death, a thing of horrible aversion, and unwilling disgust.

The process of decomposition, decay and putrescence goes on with varying degrees of rapidity, according to season, temperature and moisture, till it becomes a menace to the living, however reluctantly we may admit the painful fact; and the disagreeableness of a fact is no evidence that it is not true or that we can afford to ignore it.

In a paper read by Mr. Darwin before the London Geological Society, on the "Formation of Mould," that eminent scientist proved that in many fields every particle of the superficial layer of earth has passed through the intestines of worms. By observations in different fields he proved that in one case a depth of more than three inches of this worm mould had been accumulated in fifteen years, and in another, that earth worms had covered a bed of marl with their mould in eighty years to an average depth of thirteen inches. This is curiously confirmatory, says Sir Spencer Wells, of the recent conclusions of Pasteur, who, in his researches into the etiology of charbon, shows that this earth mould, brought up by worms, positively contains the specific germs which propagate the disease, and that these same organisms are found in the intestines of the worms. These parasitic organisms will resist the putrefactive process many years, and lie in a state of latent life like any flower-seed or grain of corn, ready to germinate and propagate the disease.

The practical inference in favor of cremation is so evident that the most sentimental objector, however blinded by prejudice, cannot fail to see it.

It now appears well established that zymotic diseases are propagated by germs; and if the much

abused Koch yet succeeds in proving the "comma bacillus" to be the *fons et origo* of cholera, there would seem to be hope of bringing that dreaded scourge to a period.

By burying in the ground a body dead of any zymotic disease, we are planting for our descendants, seed, sure, sooner or later, to bring forth a horrible crop of pestilence and death! This can no longer be doubted, or the fact ignored, for it is incontrovertibly established on the concurrent testimony of the highest scientific authority.

Dr. Freire, of Rio de Janeiro, while investigating the cause of yellow fever, found that the soil of cemeteries wherein the victims of that disease were buried, was alive with microbian organisms identical with those found in the vomit and blood of patients who had died of it in the hospital. He took samples of the earth, one foot below the surface, over the remains of a victim of yellow fever, and found them swarming with the characteristic germs. He is therefore justified in characterizing the cemeteries as the nurseries of yellow fever, the perennial foci of that dreaded disease.

Cholera already threatens us. In case it comes, and victims, few or many, die, shall we, in view of what has just been shown, plant their festering bodies in the earth, to come forth again in myriad forms, to breed additional pestilence, if possibly not for us, yet surely for our descendants, if the grave should ever be disturbed? There can be but one answer.

As yet there is but one known, sure, and never failing germicide—fire. No disease germ, it is safe to say, has ever passed through the crematory fires and survived to propagate its species.

History literally teems with accounts of epidemics caused by animal decomposition. The hygienic dangers of inhumation, *per se*, were recognized by the ancients, and repeatedly strenuous efforts were made to abolish the custom. Just as to-day a few oppose cremation, so the heathen were disputing a like question before the advent of Christianity. Why then call it "Christian burial" to permit bodies to putrefy in the darksome grave, and so possibly, nay probably, at some future day to generate "the pestilence that walketh in darkness and the destruction that wasteth at noonday."

The cause of the death of the renowned Hannibal is familiar to readers of history. He laid a siege to a city of Sicily, and wishing to build a wall of defence, tore down the old tombs to obtain material. The disturbing of so many dead bodies caused a terrible pestilence, which destroyed not only vast numbers of the Carthaginians but Hannibal himself also.

The sudden death of the vandals who broke open the coffin of Francis I., in the time of the French Revolution, to rob it of its treasures, is another familiar instance in proof of the lethal effect of the gases generated by corpses, and of their almost indefinite persistence.

The terrible scourge of cholera in London in 1854 was believed to have had its origin in the upturning of the earth in which the plague-stricken victims of the year 1665 had been buried; and the report of the London Board of Health for 1849 states that the cholera was specially prevalent and fatal in the vicinity of graveyards. Again, it is an established fact that the plague broke out afresh in Modena, Italy, in 1828, in consequence of excavations of the earth, where three

hundred years before the victims of that disease had been buried. Do we wonder that the sanitarians of Italy are enthusiastic advocates of cremation?

But it has been claimed that instances of disease caused by water and air vitiated by graves, are mostly of ancient origin, that they occurred before intramural interments were generally prohibited. They do still occur, however, though less frequently, thanks to the efforts of sanitarians, as can readily be shown. Dr. Santa vouches for the fact that a severe epidemic of fever was caused, but a few years ago, by drinking water poisoned by graveyard soakings in the villages of Bellita and Rotendella, Italy. More recently even the Monumental Cemetery at Milan was proved to have been the cause of severe illness in its vicinity, the wells being the channels of infection. The so-called Roman fever has usually been attributed to malaria from the Pontine marshes. No doubt they are dangerous enough and produce their share of miasm, but now come Sir Lyon Playfair and other sanitarians, contending, and reasonably, that a more probable, or at least an additional cause of the peculiar fever of the Eternal City exists in its soils and that of its environs, saturated as it has been for centuries with the decaying remains of its millions of buried dead.

In our own country, the *Atlanta Medical Journal* recently reported the case of two young ladies, who drank water from a spring situated on a hillside near an old graveyard, one of whom died soon after of diarrhoea and pyæmia, and the other of typhoid fever. Cattle also drank the water and were made sick. The fact is vouched for, that whenever cholera or yellow fever has visited New York city, it has prevailed especially in the vicinity of Trinity church-yard; and two years ago this spring, that same neighborhood suffered severely from typhoid fever when it was not prevalent in other parts of the city. Washington Square, New York city, was for a long time used as a Potter's Field. In 1806 it was converted into a public Square, and for years after, as the oldest physicians testify, it was almost impossible to rear children on the ground floors of houses in that vicinity.

When, a few years ago, the old disused cemetery in Mechanic Street, Worcester, was removed, hundreds of loads of the superfluous gravel were spread broadcast upon our streets. I feared that disease might result and was on the watch for it. I had many cases of severe sore throat, diarrhoea and fever in that locality, which I believe was caused by poisonous emanations from that saturated soil. That the city escaped an epidemic of some pestilential disease was no doubt due to the fact that probably no one there interred had died of cholera, yellow fever, or small-pox. My fears were considered unnecessary by my professional brethren at that time, but I could not reply with proof, for I was not then aware, as I now am, that a severe epidemic of fever in 1813 nearly decimated a town in England from precisely such a cause.

The monstrous delusion that the mere contact of the corpse with fresh earth renders it innocuous and suffices for safe disinfection, is dissipated by overwhelming evidence. I distinctly remember my boyish scruples concerning the water of a well situated not fifty yards from graves in the churchyard adjoining my father's garden. He overcame my fears by stating the belief then held, that the earth was a purifier and

a safe depurator, and that no harm could come to that well, thirty feet deep, the pride and unailing source of supply of the neighborhood. Yet I that same autumn suffered a severe and nearly fatal attack of typhoid fever, and another member of the family was similarly affected a year later. The fever occurred when the well was low, and I have no doubt, in the light of present knowledge of such dangers, that, repulsive as is the thought, I drank water filtered through the bones of my revered ancestors buried there, and that the polluted water caused that illness. To those who criticize the advocates of cremation, quoting ancient examples only, of harm from graves, this instance will appear sufficiently recent and intimate.

Permit me here to quote the opinions of a few men who have expressed themselves emphatically upon the evils of inhumation, and whose deliberate judgment carries conviction with it.

Dr. Parkes, one of the highest authorities in the world on hygienic subjects, declares that it is a matter of notoriety that the vicinity of graveyards is unhealthy.

Sir Henry Thompson writes, "No dead body can be left in the ground without poisoning the earth, the air and the water above and about it. Within a few weeks the decomposing corpse is predated with bacteria or microbian organisms, which together with the gases generated in the putrefactive process are struggling with each other in the foul *mêlée*, each seeking to escape from its loathsome imprisonment."

Dr. Curtis, of Chicago, writing upon the evils of earth burial says, "that the dead do kill the living is only too true, and that cholera and the whole list of zymotic and infectious diseases are transmitted through the contamination of air and water supplies, is no more difficult of demonstration than it is to prove the ability of sewer gas or sewage water to propagate disease. The proximity of burial grounds to disease-infected localities is not to be explained on the theory of coincidence."

Mr. Cooper, in his work on "The Causes of Epidemics," states that the digging up of the so-called plague burying grounds in Derbyshire, England, caused an immediate outbreak of that disease, and he argues strongly that burial in the earth is always and everywhere dangerous to the living.

The French Academy of Medicine reports that the putrid emanations from Père la Chaise, Montmartre, and Montparnasse, have caused frightful diseases of the throat, fevers, and diarrhoea, to which numbers fall victims every year, and that these fatal diseases have been traced to vitiated air and water, and rage with greatest violence near cemeteries.

So great a thinker as the Earl of Beaconsfield, whose knowledge was confined to no one science, and who was ahead of his times in more respects than one, said in the House of Lords, in 1880, "What is called God's acre is not adapted to the times in which we live nor to the spirit of the age. The graveyard is an institution very prejudicial to public health, and the health of the people ought to be one of the first considerations of a statesman. The time has arrived when a safer method of disposal of the dead should be instituted." Jew or Christian, the sentiment is creditable to the memory of Disraeli.

The distinguished bishop of Manchester, referring to the consecration of a cemetery, said in the same

year. "I feel convinced that very soon we shall have to face the problem how to bury our dead out of sight with safety to the living. I hold that the earth was made for the living, not for the dead. No intelligent faith can suppose that any Christian doctrine can be affected by the manner in which, or the time in which, this mortal body crumbles into dust and sees corruption. The question must be met, for cemeteries are becoming not only a difficulty and a great expense but an actual danger."

The general consensus of opinion of sanitarians the world over, adverse to earth burial, is the surest proof that the practice is dangerous to survivors. It would almost seem that Shakespeare was inspired by a prophetic sanitary wisdom when he referred to

"The very witching time of night,  
When graveyards yawn, and hell itself breathes out  
Contagion on this world."

All the horrible results and disgusting details of poisoning from the buried dead are admitted, but it is claimed by some that they occurred in the days of intra mural internments, and that abolishing that custom terminated the danger. Nothing could be more false. Removing cemeteries to a distance only postpones the evil, and, while safer for us, entails upon those who come after us a legacy of pollution, disease germs and death, with which they will justly reproach us, and which we ought to be wise enough to prevent while we have the power. The very men who claim that earth burial is safe and that graveyards are harmless when removed to a distance, go on to recommend different methods of averting the very dangers which they claim do not exist. One advises planting groves of trees to absorb the deleterious gases, apparently aware that it is only the absorbent power of vegetation which renders the air over cemeteries at all tolerable.

Another would leave them bare that the winds of heaven may sweep over them with purifying influence. Have they forgotten that in most growing cities and towns the present suburbs will soon be built over, and that the sanitary precautions recommended in connection with burial in the earth are seldom, if ever, fully taken? Such inconsistency is inexcusable, since the weight of evidence, especially during the past ten years, shows that inhumation of dead bodies is always and everywhere perilous. To postpone or ignore the danger (excusable, perhaps, in bachelors), is unworthy of fathers of children, for the fact that the future will some day be the present, makes it the object of solicitude to all unselfish humanitarians to-day.

The greatest evil result of inhumation of the dead is undoubtedly the contamination of water.

"The rivers die into offensive pools,  
And, charged with putrid verdure, breathe a gross  
And mortal noisance into all the air."

It was, I believe, the oft-quoted Hippocrates who first formulated the requisites of health, as "pure water, pure air, and a pure soil;" and in our day the most eminent physicians maintain that polluted drinking water is by far the most frequent cause of enteric fever and other zymotic diseases; and when we consider that three-fourths of the human body and nearly as great a proportion of all our daily food consists of water, the importance of its purity is at once realized. Yet but a few years ago when Woodworth sang,

"How sweet from the green mossy brim to receive it,  
The murky-eyed bucket which hung in the well,"

the poetry was applauded, and the danger unseen. Temperance reformers complain of slow progress against the ravages of alcohol. Water has also its victims. I had almost said as many, and a part of their energies might profitably be directed as a crusade against its contamination by cesspools, drains, and cemeteries. Drains as well as drains are dangerous.

A well-recognized and, as I believe, not uncommon cause of typhoid fever is impure milk. The water for dairies appears to be of more importance than the supply of food (and I have no reference to the cupidity of the average milkman). I have personal knowledge of cases of enteric fever believed to have had their origin in milk produced by cows pastured near an old cemetery, the water which they drank being supplied by springs very near it. Thus even milk may not always be a safe beverage. The fabled founders of Rome have been considered wise in their choice of a sanitary source of supply; but even that galactophorous wolf may possibly not always have drunk from the same babbling stream with the storied lamb, but from some Roman pool of doubtful purity.

In view of what has already been shown, I venture to assert that earth burial is only an evil, and that continually. No spot of ground accessible and convenient for present use as a cemetery can be found, which will not, in the future, be liable to be needed and used as the residence of man; and the indefinite persistence of graveyard pollution has been, I hope, abundantly proved.

An old well on the old common in Worcester, which was formerly used as a cemetery, has recently been shown to be contaminated by the products of animal decomposition, no other source than the old graves being evident or probable.

Professor Pumpelly has ascertained by recent experiments that sandy soil interposes absolutely no barrier between wells and the bacterial infection from cemeteries and cesspools lying even at a considerable distance from them. Indeed he claims further, that "dry gravel and coarse sand do not prevent the entrance into houses built upon them, of those micro-organisms which swarm in the ground air, around leaky cesspools, near graveyards, and in the filthy made land of cities." Not even the filters employed in the laboratories have been quite effectual in preventing the passage of those many named microbes which are now recognized as the cause of the transmission of disease.

So well recognized is the fact of the danger of the poisoning of water by graves that laws exist in France prohibiting the opening of wells within one hundred yards of any place of burial; and in some of the German states it is forbidden by law to dig wells nearer than three hundred yards to any grave; and at a hygienic council, held some time ago in Brussels, it was decided that the safe protective distance should not be less than four hundred yards. In our country I am not aware that any such laws exist. In Philadelphia, three cemeteries estimated to contain 80,000 graves are so situated as to be liable to drain into the Schuylkill, above Fairmount dam, whence is drawn the city's water supply. The "Centennial diarrhoea," so called, had a cause other than exhaustion from too much sight seeing. Many eminent sanitarians now believe that cause was graveyard pollution of water, drunk by strangers unaccustomed to it.

It may appear that the title of this paper should

have been more appropriately "the dangers of earth burial," but I may reply that in demonstrating such universal and inevitable dangers, not only at present but for posterity, I have proved the urgent necessity for cremation, for, so far as is yet known, all other proposed or practised methods of disposal of the dead are defective and impracticable, in our country at least. They have little to recommend them anywhere. "Exposure," practised by the Parsees and other tribes of India, the body being left where it can be devoured by wild beasts or torn by birds of prey, seems cruel and barbarous, and is not even desirable in a sanitary view, for I am told by my friend, Dr. Peabody, of Worcester, who has lived in Bombay, that the vultures frequently dropped large masses of flesh where they became offensive to the inhabitants. We are hardly ready to erect "towers of silence," or to suspend our dead upon the limbs of trees to be disposed of in such a manner. The Hindoos expose their dead upon the banks of their sacred river, to be the prey of their river monsters. Burial at sea is only one form of exposure, for marine animals soon devour the corpse.

Embalming, mummifying, or desiccating, as practised by the Egyptians for ages, is disgusting, imperfect and unsatisfactory. Such effort to preserve the body is always only partial, the resulting object being horrible, ghastly and distressing to behold. The sight of such of these ancient relics as I have encountered in the Smithsonian Institution at Washington, in the Museum of the Royal College of Surgeons in London, and elsewhere, is quite enough to disenchanted any one who might aspire to have his dead body set up in that odoriferous and obsolete style.

Various other methods of rendering the corpse harmless have been proposed. One believes it possible to destroy all living germs in a dead body by injecting the blood-vessels with chemical reagents known to be deadly to these organisms. He suggests one of the soluble salts of mercury as the most deadly of protoplasmic poisons. Another suggests covering the uncoiled body in the grave with quicklime to hasten the process of decomposition; but it is difficult to see how this would be any less revolting to the feelings of friends than is cremation by the present scientific and decorous method. The ancient form of cremation or fire burial, the "feiner bestattung" of the ancient Germans, and the funeral pyre of which so much is written in the classics, was disgusting and open to many of the objections now urged against earth burial. The corpse placed upon a pile of wood, the "pyra" gave forth the most nauseating smells, to counteract which expensive gums and essences were consumed with it in extravagant quantities, while with rich flames and hired tears they solemnized their obsequies.

Modern cremation is stripped of all these objectionable features. The body is totally consumed in an hour, or two at most, leaving only a few pounds of harmless residuum, and all without the least odor or offence to the most fastidious sense.

The problem is, given a dead body, sure in a few days to become dangerous to the living, how shall we dispose of it reverently and with absolute safety to survivors, both now and hereafter forever. The answer is by fire, all-purifying fire, the element which when uncontrolled is no doubt the ruthless and destroying enemy of man, but when under control is his servant and friend. Indeed "the ethereal fire has

been the most sacred symbol in nearly every varying faith of the world of the visible presence of God." The followers of Zoroaster are not the only worshippers of the sun. There are "Fire Worshipers" in our day, and their number increases as the sanitary value of fire becomes known. Fire will destroy absolutely every form of disease germ, while no degree of freezing will do so. Pork may be exposed through an arctic winter, then thawed and found to propagate the trichinosis disease. Cold does not destroy animalculæ, for they abound in ice water. Heat will utterly destroy the cryptogamic spore and annihilate the mycelium, but freezing only affords them a temporary rest. All other disinfectants are feeble and ineffectual when compared with the all-purifying fire. Indeed many devastating conflagrations which in cities have been deplored as calamities have really been blessings in disguise as disinfectants and promoters of health. The great fire of London, as is well known, terminated the plague and purified that pestilential city. The ancient rabbis tell us that in times of pestilence, fires were kept burning in the valley of Tophet to consume the dead and to disinfect the air.

Scientific apparatus has now been devised capable of reducing a human body to ashes safely, quickly, and not unpleasantly. There is offered to the people a custom which will forever annihilate the dangers set forth in this essay, the contamination of earth, air and water, the liability to burial alive, the sacrilegious work of grave robbers, and much of the unnecessary expense of funerals.

Reason everywhere approves the reforms, and sentiment alone opposes it. Sentiment is always to be regarded when the safety of the people is not jeopardized thereby. Otherwise it is our duty to strive to substitute for exuberance of sentiment, persuasive reason.

Let us then boldly advocate this reform, for whatever opposition we meet to-day, there can be no doubt of the favorable verdict of posterity upon our action.

That cremation has won its way so slowly until within the past ten years, only proves again how slow and dillicult it ever is to stem the tide of popular prejudice and institute measures of any sanitary reform. Recently, however, the recognition of its merits has imparted to its advocacy a new impetus in all civilized countries, and while I would not mistake the crowing of the cock for the rising of the sun, I may predict that this greatest of sanitary reforms is destined to prevail in the near future.

A Fellow of this Society contributed to the Report of our State Board of Health, for the year 1875, an able paper upon "Cremation and Burial." He arrived at the conclusion that incineration of the dead was not then a sanitary necessity. This opinion was based largely upon the negative testimony of a large number of physicians in this State, who had not probably given much attention to the subject. A decade of sanitary investigation having passed, the dangers of internment having become more evident, and the scientific process of cremation having become more perfected, I doubt if he would now arrive at the same conclusion after a similar amount of research.

The only objection to cremation, founded in reason and not sentiment, is, that the practice might destroy evidence of crime. Lack of time forbids me to answer this objection *in extenso*. I may say, however, that Lucretia Borgias are extremely rare in our

day, and that even if cases of criminal poisoning and other crimes against life and health were far more common than they now are, instances of disease and death, due to the evil effects of inhumation, are believed to outnumber, by far, cases of undetected crime which could possibly be due to the adoption of incineration; and, on the principle of the greatest good to the greatest number even, the proposed reform would still be justified.

Though the sanitary is the chief argument in favor of cremation, there are other important reasons for its adoption. The genus "Jerry Cruncher" is not extinct. Remember that the remains of your dearest friend are never secure from the unholty rapacity of the grave robber. It seems almost a pity to disturb the illusive dream that cemeteries are sleeping places of the dead, as the name implies, yet it is a pathetic fact that neither the body of the pauper, buried without a tear, that of the millionaire committed to the vault with more than royal magnificence, not even that of a martyred president, placed in the tomb protected by bolts and bars, is safe from the sacrilegious hand of the resurrectionist. "Body snatching" is shockingly common.

Again, the danger of *burial alive* is not wholly chimerical. A work recently published in Italy reports sixty-five authenticated cases of burial of persons afterwards discovered to have been alive at the time. In this country we often read of persons being resuscitated from what appeared to be the sleep of death. Cremation being the practice, this inexpressibly horrible calamity would be impossible, and if by any accident a body not already dead were to be placed in the crematory furnace, death would be instantaneous and painless.

Again, should cremation become general, the *expense* of the proper and decent disposal of our dead could be greatly reduced. True, the poor as well as the rich could still, if so disposed, waste their means, or those of their friends, on splendid collins, richly pallid, stately hearse adorned with gaudy plumes, gaily caparisoned horses, and all the superfluous paraphernalia of worldly war, for

"The earth hath bubbles, as the water has,  
And these are of them;"

but these trappings are not necessary, and when our work on earth is done, we need not cause our friends, overwhelmed per chance by grief, to be also weighed down by debt in order to dispose of our mortal remains respectably. A showy funeral is a hollow mockery, a relic of barbarism. Pride and ostentation in the presence of the great destroyer, are painfully inappropriate. Simplicity, quiet, and decorum should here prevail. Instead we see extravagance, a noisy brass band, feathers and plumes. With cremation a part, at least, of this Vanity Fair could be abolished. A strange and holy mystery is death, and Christian people should be able to devise more modest methods of disposal for its silent victims.

However unpleasant the choice of evils, no sanitation can hesitate between Estrina and Golgotha. "The place of a burning" or "the place of a skull" is, so far as is yet demonstrated, the inevitable alternative.

"Instead, therefore, of thrusting our loved ones who have departed this life into the gloomy grave, there to fester in loathsome putrefaction, and thence

to come forth in ghastly forms of dreaded disease, let us reverently, decorously, and expeditiously translate them by means of the all-purifying fire into the elements of all new and beautiful life. So shall our fair land become indeed, as it should be, the land of the living, and not the valley of the shadow of death."

#### APPENDIX. — THE MASSACHUSETTS LAW REGARDING CREMATION.

An Act authorizing the formation of Corporations for the purpose of Cremating the Bodies of the Dead.

*Be it enacted, etc., as follows:—*

SECTION 1. Any five or more persons may associate themselves together in the manner prescribed by chapter one hundred and six of the Public Statutes, with a capital of not less than six thousand, or more than fifty thousand dollars, for the purpose of providing the necessary appliances and facilities for the proper disposal by incineration of the bodies of the dead; any corporation so established shall have the same powers and privileges and be subject to the same duties, liabilities, and restrictions as other corporations established under said chapter, except as herein-after provided. The *par value of shares* in the capital stock of corporations organized under the provisions of this act shall be *either ten or fifty dollars*.

SECT. 2. Every such corporation may acquire by gift, devise or purchase, and hold in fee simple so much real estate not exceeding in value fifty thousand dollars, as may be necessary for carrying out the objects connected with and appropriate to the purposes of said corporation, and situated in such place as the State Board of Health, Lunacy, and Charity may determine to be suitable for said objects and purposes. No building shall be erected, occupied or used by such corporation until the location and plans thereof, with all details of construction, have been submitted to and approved by said board or some person designated by it to examine them.

SECT. 3. Every such corporation may make by-laws and regulations consistent with law and subject to the approval of said state board, for the reception and cremation of bodies of deceased persons, and for the disposition of the ashes remaining therefrom, and shall carry on all its business in accordance with such regulations as said board shall from time to time establish and furnish in writing to the clerk of the corporation, and for each violation of said regulations it shall forfeit not less than twenty nor more than five hundred dollars.

SECT. 4. No body of a deceased person shall be cremated within forty-eight hours after decease, unless death was occasioned by contagious or infectious disease; and no body shall be received or cremated by said corporation until its officers have received the certificate or burial permit required by law before burial, together with a certificate from the medical examiner of the district within which the death occurred, that he has viewed the body and made personal inquiry into the cause and manner of death, and is of opinion that no further examination nor judicial inquiry concerning the same is necessary. For such view, inquiry and certificate he shall receive the fees prescribed by section nine of chapter twenty-six of the Public Statutes for a view without an autopsy by examiners in counties other than Suffolk County. Medical examiners within their respective districts

shall make such view and inquiry upon application therefor and payment or tender of said fees.

SECT. 5. This act shall take effect upon its passage.

Approved, May 26, 1885.

## Reports of Societies.

### THE AMERICAN OPHTHALMOLOGICAL SOCIETY.<sup>1</sup>

THURSDAY MORNING. — PNEUMOPHTHALMOS: OR AIR IN THE VITREOUS HUMOR.

By DR. W. F. MITTENDORF, of New York.

The entrance of air into the interior of the eye will occur at times during an operation, as, for instance, a cataract extraction. In such cases the air may get into the anterior chamber, whence it can be removed with ease. It is, however, entirely different when air gets into the vitreous chamber. Fortunately, this accident is of such rare occurrence that so far no description of it has been given. The writer had seen two cases of this kind within the last two years. Both occurred in connection with injuries caused by the entrance of foreign bodies into the interior of the eye. Such accidents are usually so serious that any complication of them becomes a matter of great interest. The first case was that of a young blacksmith who was wounded by a piece of iron penetrating the sclera and lodging in the vitreous humor. The foreign body, surrounded by a clot of blood, was found at the bottom of the eye. Behind the lens and a little above it, three air-bubbles were seen by means of the ophthalmoscope. These appeared to be of the size of a small pea, the smallest about as large as a rapeseed. They closely resembled the air-bubble as seen under the microscope, their centres being bright and the outlines well defined and surrounded by a sharp, black border. Their recognition was not difficult. The foreign body could not be removed with the magnet, and it was decided to allow it to remain. The eye was carefully bandaged, and the day following it was found that the air-bubbles had united and were located at the posterior pole of the lens, the patient having remained quietly on his back some time before the examination. While he was in the upright position the air began to rise slowly until it reached the upper part of the vitreous chamber. During this trip the bubble looked oval and decidedly pointed at its lower portion, resembling oil globules as they are seen ascending in water. Forty-eight hours after the accident every trace of the air-bubbles had disappeared.

The second case reported was the result of a drilling accident. A pretty large piece of stone or iron had perforated the sclera at the lower and outer part of the eye. In the semi-transparent vitreous an air-bubble of the size of a hempseed could be seen distinctly.

In order to determine the exact appearance of air in the vitreous, the writer experimented upon rabbits' eyes. Four of them had air introduced into the vitreous humor by means of a hypodermic syringe, and four were subjected to the introduction of oil, also by means of the hypodermic syringe. Nearly all these experiments were successful. The difference between the air and the oil bubble was so marked that they could

be readily diagnosed by means of the ophthalmoscope. The latter were more highly refractive, heavier in appearance, and the contour decidedly darker than the air-bubbles, which were entirely colorless.

The conclusions reached by the author were as follows:—

(1) The entrance of air into the vitreous body can occur only after a part of the contents of the vitreous chamber has escaped.

(2) It is favored by the entrance of a foreign body which makes a large gaping, irregular wound of the sclera.

(3) In order to allow air to enter the vitreous humor, this must either be quite fluid or its anatomical arrangement must have been disturbed by the entrance of a foreign body, or the air must have been attached to the foreign body and be thus carried with it into the eye.

(4) The air in the vitreous humor appears like an air-bubble as seen under the microscope; it is more or less round, highly refractive in the centre, and has a sharply defined black outline.

(5) Oil globules in the vitreous present a similar appearance, but they look heavier, are not perfectly colorless, and their outlines are darker; they are more glittering in the centre.

(6) Air-bubbles will be completely absorbed within two or three days; their presence is not a source of great danger to the eye. Oil globules last longer, but they are likewise non-irritating.

### A CASE OF TUBERCLE OF THE IRIS.

By MYLES STANDISH, M.D., of Boston.

The patient was a girl fourteen years of age; both parents were living and had never presented any evidences of syphilitic or tuberculous disease. Two brothers and one sister, all younger than the patient, are living and well. There is absolutely nothing of a specific character in the history of the patient or her brothers and sister. During the past winter she was confined to bed with intense pain in the epigastrium, and acute hepatic ascitis was the diagnosis reached by the family physician. No pulmonary lesion was detected.

At the time she came under observation of the speaker, she complained of feeling run down and was anemic and poorly developed. The eye trouble had existed for four weeks. There had not been much pain or photophobia.

Examination of the eye showed the iris attached by its pupillary margin to the capsule of the lens, somewhat atrophied in appearance. On it there was a growth, 2 mm. in diameter, pink in color, with small vessels on its surface. The growth projected from the iris near its ciliary border. Various mydriatics were employed without any effect upon the pupil.

In the course of a month the growth had doubled its size, the conjunctiva and iris remaining perfectly clear. Other growths made their appearance, and after consultation with Dr. Wadsworth, the eye was removed at the Massachusetts General Hospital.

Examination after emulsion showed the vitreous retina, and choroid to be normal. The lens was somewhat opaque. The iris was very adherent to the capsule of the lens along its pupillary border, and also beneath the entire area of the principal growth. The largest mass sprang from the surface of the iris near its ciliary border, and at its base was 2.5 mm. in diameter,

<sup>1</sup> Concluded from page 107.

and was 2 mm. in height. At the top its diameter was 4 mm. This was apparently due to the pressure of the growth against the cornea. There were three other growths, but none of them involved the ciliary body or even the ciliary border of the iris. Dr. Ernst, of Boston, made the microscopical examination. The ordinary evidences of tubercle were found and the bacillus tuberculosis was detected.

Dr. KNAPP had seen growths presenting exactly the same appearance which had disappeared under the use of specific treatment with mercury even where there was no evidence of syphilis. He had never felt warranted in making the diagnosis of tubercle in such cases, although the presence of the tubercle bacilli in this case would seem to confirm the diagnosis.

#### A CASE OF CONGENITAL COLOBOMA OF THE IRIS, CHOROID, ETC.,

was reported by Dr. C. J. KIPP, of Newark.

The patient was a woman sixty-nine years of age. She was first seen four years ago. There were at that time no inflammatory symptoms, but a small triangular coloboma of the iris was found exactly in the vertical meridian. The tension was above normal. The patient had never seen with this eye, but it had never given pain. Four years later the patient was again seen, and the eye presented the signs of inflammatory glaucoma; the pain had prevented sleep for many weeks. The eye was enucleated and healed promptly. There was also found a large cecastia of the sclerotic, and over this the choroid and retina were wanting. The cecastia extended close to the optic papule. There was also a deep kettle-shaped excavation of the optic nerve.

#### COLOBOMA OF THE CHOROID ON THE TEMPORAL SIDE.

By Dr. S. D. RISLEY, of Philadelphia.

A young physician consulted Dr. Risley for asthenopia. There was a considerable degree of myopia in the left eye. In the right eye vision was much diminished =  $\frac{2}{8}$ . The ophthalmoscope showed a large hiatus in the choroid on the temporal side, the depth of which was 3 d. There had been no pain. The speaker thought that these cases were comparatively rare.

Dr. MITTENDORF had seen several of these excavations in the outward direction. Where the coloboma was so deep it was, he thought, probably a coloboma of the optic nerve sheath with excavation of the nerve. A difference of 1 d. would indicate a greater defect than would correspond to absence of choroid and retina alone.

#### SEROUS EFFUSION IN THE VITREOUS DUE TO MALARIA.

By Dr. W. W. SEELY, of Cincinnati.

The speaker considered the occurrence of this complication not infrequent, and he reported one case of this affection.

#### GRAY DEGENERATION OF THE OPTIC NERVE, WITH ABNORMAL PATILLA REFLEX.

By Dr. WM. F. NORRIS.

After an elaborate review of the literature of the subject the speaker gave the results of his observations in cases in which the patilla reflex was increased or diminished. He described three cases of gray degeneration associated with tabes dorsalis, which had come

under his observation. While he did not hold that this symptom indicated beginning tabes dorsalis, yet it was a danger-signal calling for rest of the brain and cord, with attention to improvement of the general condition.

#### A CASE OF DOUBLE OPTIC NEURITIS AND OPHTHALMOPLEGIA FROM LEAD-POISONING COMPLICATED WITH TYPHOID FEVER.

By Dr. O. F. WADSWORTH, of Boston.

A boy of nine years of age had suffered from obscure febrile symptoms for several weeks, and movements of the left eye had been observed to be imperfect. When first seen by Dr. Wadsworth there was pronounced optic neuritis in both eyes. The rest of the fundus normal; vision was much diminished; no lateral movements of left eye could be made, and movement downward was impaired. The outward movement of right eye was defective. The probable diagnosis was tumor in the region of the pons.

The movements of the eyes became still more impaired and vision sank. The boy developed pretty distinct symptoms of typhoid fever; the spleen and liver were both enlarged; lead was found in the urine, and the diagnosis of tumor was then abandoned. The treatment was with iodide of potassium. The general condition gradually improved; the neuritis passed into atrophy, leaving too little vision to count fingers. The movements of the eyes were completely restored, and the lead disappeared from the urine. The cause of the lead-poisoning was found to be the presence of a piece of lead pipe in the cistern from which the drinking-water was obtained.

#### OLIVE OIL AS A MENSTRUUM FOR DISSOLVING COCAINE FOR APPLICATION TO THE EYE.

By Dr. JOSEPH A. ANDREWS, of New York.

In addition to the occasional benefit from the use of oil dropped into the eye in recent abrasions from burns and in other painful affections of the cornea in which atropia is indicated, cocaine may likewise be serviceable. The plan of dissolving the cocaine in oil seems to insure a longer contact of the remedy, and a smaller quantity is required to effect anaesthesia, — two qualities of especial advantage in operations on the eye.

Neither the salt of cocaine nor of atropia is soluble in olive oil, but the alkaloid of both dissolves readily in the menstruum without the addition of an acid, it being only necessary to expose the solution for a few minutes to a gentle heat in a water bath. Castor oil is not a desirable menstruum on account of its irritating qualities, and the oleate of cocaine, for the same reason, is still more objectionable as an application to the eye.

A case in which enucleation of the eye for glaucoma had precipitated glaucoma in the other eye was reported by Dr. DAVID WEBSTER, of New York. The patient was a man of fifty-four, the subject of glaucoma absolutum. He complained of periodical obscurations of vision in the good eye.  $V = \frac{2}{8}$ , and there was no limitation of the visual field. As he was of dissipated habits he was advised to live properly. A week or two later, returned, stating that he had a worse attack. There was an excavation of the nerve in the good eye detected. The glaucomatous eye was now removed. Two days later acute glaucoma appeared. An iridectomy was performed, and he recovered in a week or two with  $V = \frac{20}{20}$ , with no cupping of the disk and

no limitation of the field. This was the only case he knew of in which enucleation had precipitated an attack of acute glaucoma in an eye already predisposed to it. He had, however, reported cases in which iridectomy had produced the same effect.

#### QUININE AMAUROSIS.

By DR. E. WILLIAMS, of Cincinnati.

The speaker reported two cases. In the first case a man took about one ounce in the course of four days. This produced total blindness and deafness, but in six days he could see as well as ever. The hearing had never completely returned, although the quinine was taken eight years ago. The field of vision was concentrically contracted in both eyes. The optic disks were very white, the calibre of the arteries and veins was reduced, and the smaller capillaries could not be seen.

The second case was that of a boy of fourteen, who had received large doses of quinine, the exact amount not being known. He was totally blind for four days. When examined the sight was much diminished, the atrophy of the optic disks was extreme, and there was great contraction of the field of vision.

#### A MEANS OF MEASUREMENT OF THE AMOUNT OF ANÆSTHESIA FROM COCAINE.

By DR. LUCIEN HOWE, of Buffalo.

The speaker exhibited a drawing of a kymograph which he had used for this purpose. The use of the instrument was based on the fact that irritation of a sensory nerve is followed by a rise of blood pressure. The instrument is connected with an artery, and the conjunctiva is irritated. Cocaine may then be applied, and the results on the blood-pressure compared.

DR. HARLAN, of Philadelphia, presented a modified ophthalmoscope which had been devised by Dr. Jackson, of Philadelphia. In it the lenses moved vertically instead of circularly.

DR. DENNET, of New York, exhibited an arrangement for using Stokes's lens for measuring astigmatism and to avoid the inconvenience of constantly removing the frame from the patient's nose. The lens was mounted on a stand, and could thus be placed in front of the patient.

DR. B. JOY JEFFRIES, of Boston, offered the following resolution concerning

#### STANDARD COLOR SIGNALS.

which was unanimously adopted:

*Resolved*, That the Society would again express most hearty approval of the International Commission, twice recommended in a bill reported by the Naval Committee of Congress, and endorsed by the International Medical Congress of London, 1881; to consider and agree upon standard colored lights and signals, etc.; and the visual power and color sense of officers and sailors.

The Society would particularly support the International Commission, and vote that "every government, especially the maritime governments, should be requested to place one or more members on the Commission, and chiefly experienced naval officers and medical specialists."

The Secretary is hereby directed to transmit this vote to Congress.

DR. SAMUEL THEOBALD, of Baltimore, offered the following resolution concerning the

#### NEW ORGANIZATION OF THE INTERNATIONAL CONGRESS.

*Resolved*, That it is the sense of the American Ophthalmological Society, that the action of the American Medical Association, at its late meeting in New Orleans, and of the enlarged committee appointed at that time to make arrangements for the International Medical Congress, in overturning much of the carefully planned work of the original committee appointed at Washington, for the same purpose, was unwise, and not to be defended, unless, possibly, upon technical grounds; and this Society hopes that none of its members will endorse the action of the enlarged committee by accepting official positions at its hands.

DR. E. WILLIAMS, of Cincinnati, voted against the measure. He understood that he was appointed by the new committee president of the Ophthalmological Section, but up to the present time he had not been notified, and hence had not yet tendered his resignation.

DR. KIRP spoke against the resolution.

The resolution was adopted by a large majority.

The officers for the ensuing year are as follows: President, Dr. William F. Norris, of Philadelphia. Vice-president, Dr. Haskett Derby, of Boston. Secretary and Treasurer, Dr. O. F. Wadsworth, of Boston. Corresponding Secretary, Dr. J. G. Prout, of Brooklyn.

New members were elected as follows: Dr. Charles A. Oliver, of Philadelphia; Dr. Edward Jackson, of Philadelphia; Dr. B. Alexander Randall, of Philadelphia; Dr. D. Pope Walker, of New York; Dr. William O. Moore, of New York; Dr. Frank Capron, of Providence; Dr. S. M. Burnett, of Washington; Dr. William T. Bacon, of Hartford.

The next meeting will be held at New London, the third Wednesday in July, 1886.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting June 4, 1885.

#### CONTAGIOUS OPHTHALMIA IN SOME OF THE ORPHAN ASYLUMS AND RESIDENTIAL SCHOOLS OF NEW YORK CITY.

DR. RICHARD H. DERRY read a paper on this subject, which gave the results of his personal examinations of the eyes of the children in twenty-four of these institutions. Any inmate of them, he said, was far more liable to lose his sight from this disease than to lose his life from scarlet fever or other zymotic affection. The disease, however, he believed to be amenable to treatment, and it seemed to him inexcusable on the part of both the profession and the public to longer neglect to put a stop to its ravages, in view of its wide extent and constantly increasing prevalence. This affection was a blepharorrhoeic conjunctivitis, the secretions in which are highly contagious; the infection being perhaps most frequently communicated by children using the same towels and washing in the same water. In serious cases the cornea and almost all the structures of the eye became involved.

In the first asylum which he visited, out of 326 boys, 96 were affected by the disease, and out of 331 girls, 65, or 24.5 per cent altogether. In the second visited institution, out of 1,586 children, there were 188 cases, or 30.7 per cent; while in the third there were no less than 93 cases out of 188, making the

enormous percentage of 49.4. The total number of children examined was 7,440, and the total number of cases of contagious eye-disease found, 1,428, or 19.19 per cent. When the disease became usually bad in any of these institutions, it was the common practice to send the children to their tenement-house homes; but this was a serious mistake, as either the treatment was apt to be entirely neglected there or else it put too much of a burden upon their over-taxed parents or friends, while each became a focus for the dissemination of the affection through the community at large.

In concluding his report, Dr. Derby made several suggestions, as follows: That all asylums or residential schools should be required by law to adopt the most stringent rules for the prevention of contagious eye-disease, in regard to towels, washing in common, etc.; that they should be required to present to the Board of Health at certain specified intervals a statement of the number of existing cases; that they should be required to separate all those suffering from it from the other inmates; that they should be required to provide adequate treatment, not merely local, but hygienic and general, in every case; and that they should be required to adopt the same precautions to prevent the spread of the disease as are commonly employed in the case of scarlet fever, diphtheria, etc. It was evident, he said, on account of the present enormous extent to which the disease prevailed in these institutions, that it seemed to him that a special hospital — which there are already more than enough cases to fill — was needed for the successful treatment of such a dangerous affection. In view of these circumstances, therefore, he called upon the Academy of Medicine to take some definite action toward the suppression of this crying evil.

#### DISCUSSION.

Dr. H. KNAPP said that he could not conscientiously underrate the importance and force of the statements made by Dr. Derby. Sometimes the disease in question prevailed to such an alarming extent that the managers of institutions were obliged to close them entirely for a time and turn the inmates out. Unfortunately, however, when this was done, the affected children were often the means of spreading the disease more or less widely through the community. Some of the asylums and schools, he knew, took the most active measures to stamp out the disease among their inmates; but it was a fact that, when they had once been invaded by it, a certain number of cases were almost sure to be found in them, all the time. He therefore doubted whether the disease was in reality altogether preventable. He felt sure, however, that those in charge of some of the institutions did what they could to put it under control. The managers of two of them, which he mentioned by name, invariably sent to him (Dr. Knapp) every candidate for admission so that he might examine the condition of the child's eyes before it was permitted to enter. He thought that Dr. Derby's suggestion that a certain supervision should be maintained over the eyes of the children in all these institutions a most excellent one, and if from time to time careful inspections were made by competent physicians, and the report of the results of the same transmitted to the proper authorities, he believed that large epidemics at least of contagious ophthalmia would in the future be avoided.

Dr. ROOSA said that he did not consider the authorities of the institutions altogether to blame for the existing state of affairs, but thought that the Board of Health was responsible to a large extent. The public interest that he excited in this matter of eye-disease in children had, however, he believed, already borne considerable fruit. Still, much, of course, remained to be done. The remedy for the evil was at hand, and to be obtained with perfect ease. The taxpayers of the city should be made to pay for the establishment and support of such a special hospital as Dr. Derby had suggested. The cost to the State of men with poor eyes, or altogether blind, was a very serious matter, and the reduction of the pauper class was certainly important enough to engage the attention of the politicophilanthropist. The Board of Health, he thought, should at once take measures for the establishment of such a hospital.

Dr. AGNEW said that his interest in the subject of contagious ophthalmia began nearly thirty years ago in Ireland, where, in connection with the famine, the disease developed in the poorhouses and other public institutions. At that time he saw an immense number of lids there, and from this stock, he said, the United States had been receiving fresh importations ever since. He had hoped that in the State of New York he would never be called upon to witness such scenes as he had in some of our institutions. He then gave an account of an attempt to develop an orphan asylum in a neighboring county, where the available funds were entirely inadequate for the purpose. In a building which was totally unfit for this use nearly three hundred children were packed, a much larger number than it could properly accommodate. The hygienic conditions were thus very poor, and contagious ophthalmia soon broke out. The children all washed in a trough sixteen feet long, and by this means the disease was communicated to eight tenths of those who came in from outside. What made the disease all the worse was the fact that in the infirmary the children had to sleep two or three in a bed. There was a gentleman now present at the Academy who had taken charge of the children at that time, and who had brought about a complete revolution. He turned all the children out of doors into two large circus tents, and instead of keeping them upon ten or fifteen quarts of milk a day, as had previously been done, he allowed them to have four hundred quarts. This was a fair type of a considerable number of institutions which were all the time taking children for whom they were altogether unable to suitably provide; and he thought, therefore, that a thorough system of inspection should be established in all these schools and asylums. He did not like the idea of entrusting such a matter to the State; but there was no limit to individualism and the power of voluntary efforts.

It seemed evident to him, then, that there was need of some legislation in the matter. He believed in agitation of a subject, and it was his opinion that by judicious efforts on the part of those specially interested the public mind could soon be brought to realize the necessity for the adoption of active measures for repressing the evil. A few years ago the vile condition of the vessels bringing immigrants to our shores was such that ship-fever was of constant occurrence; the passengers being subjected to as much overcrowding and bad treatment generally as the negroes in the slave-ships. This state of affairs continued until pub-

lie opinion became roused to a sufficient extent to cause the adoption and enforcement of three wise and beneficial rules which now invariably regulate the carrying of steerage-passengers. He thought that before an institution for the care of children should be allowed to have a corporate existence, it should deposit with the proper authorities a certificate specifying the number of inmates which it could suitably accommodate, and that it should never be permitted, under any circumstances, to receive more than this number. The State Board of Charities, he believed, ought to take some action in regard to this important matter. The managers of the various institutions were almost, without exception, disposed to do what was right. They are perfectly willing to act for the best interests of the children committed to their charge, but were ignorant of the proper methods to pursue. It was indeed terrifying to think of making six or seven hundred paupers in the residential schools of New York, and it is high time that something was being done to put a stop to the existing state of affairs. It was his opinion that the vast number of children who contracted chronic conjunctivitis in these institutions never recovered from it, and in after life they constituted an immense body of drifting, despairing sufferers, in many instances wandering aimlessly about from one dispensary to another. A few years ago it used to be the boast of Fourth-of-July orators that there were no indigenous paupers in this country; but now all this was changed, and at present there was unquestionably a large amount of indigenous pauperism here.

After remarks by Mr. Elbridge T. Gerry, President of the Society for the Prevention of Cruelty to Children, and Dr. J. J. Milhan, of the State Board of Charities, the President, Dr. Jacobi, said that in his opinion this disease could never be eradicated as long as an institution in which an outbreak of it occurred remained on the same spot and continued to have inmates. Outbreaks of ophthalmia were liable to occur, notwithstanding all the measures which might be adopted to prevent them, just as scarlet fever or measles was liable to break out among the children in these institutions, which were designed and expected to do good, but which in reality accomplished a great deal of harm. Measles, as it generally appeared in private families, was a mild disease; but in public institutions it was often very fatal. We believe it would be very much better if children were left in the tenement-houses than entrusted to the care of institutions. These institutions were always over-crowded, and whenever a disease like measles or whooping-cough broke out among the inmates, the results were apt to be very serious. Whooping-cough, like measles, was not under ordinary circumstances a very grave affection, but among children thus crowded together it often proved fatal; and when this was not the case, was likely to be followed by disastrous consequences. Very frequently phthisis, for instance, was the result of whooping-cough or measles contracted in early life in these institutions. If, therefore, the object contemplated by the present agitation were simply to add another to our already numerous hospitals, he did not think much good would be accomplished by it. In such an institution for the treatment of contagious eye-diseases he could not doubt that many cases which were mild when admitted would assume a severe type, and that the danger would be increased rather than

diminished, by placing children in it. The question had already come up all over Europe, and was now coming up here, whether these institutions for children ought to be multiplied at all; and for his part he felt convinced that it would be a benefit to the community if these public institutions were done away with altogether. If the same money now expended for the erection and maintenance of splendid buildings, and the same care now bestowed upon their management, were given to farming the children out in a suitable manner, he believed that we should be much better off. There would be more children alive, and fewer blind ones than we have at present.

DR. MITTENDORF said that there were two points which the public did not understand, namely, that the disease in question was extremely contagious, and that when it had once made its appearance in an institution it could not be eradicated. He agreed with Dr. Jacobi as to the evils associated with public institutions. In the country branches of the New York Infant Asylum and of the Nursery and Child's Hospital the plan had been adopted of placing a few children in separate cottages, and the results had been much better than when a large number of them were crowded together. The best plan at present seemed, therefore, to have a number of small buildings and to place as few children as possible in each one. When contagious ophthalmia broke out in an institution, he thought that the patients should be kept in it, but strictly isolated. It was unadvisable to send them to a general eye-hospital, for the reason that the disease was likely to spread to other patients, and in an institution where delicate operations were constantly being performed this could be followed by serious consequences.

DR. AGNEW then presented resolutions setting forth that it was necessary and expedient that steps should be taken to put a stop to the contagious eye disease prevalent in the asylums and residential schools of the city, and requesting the Council of the Academy of Medicine to act in connection with the author of this paper, the State Board of Charities, the Society for the Prevention of Cruelty to Children, and other charitable organizations in appointing a joint committee to devise a suitable plan for the accomplishment of the desired object.

In seconding the resolutions, DR. ROOSA said that it was necessary to take things as they are, and not as they might be under a Utopian state of affairs. In his opinion the disease could be successfully stamped out, and he thought this could most easily be accomplished by means of a special hospital, as had been proposed. Such a hospital need not be a permanent institution but only a temporary agency.

— DR. ELSON, as surgeon of the First Division of the National Guard, is organizing an ambulance corps for service on the day of General Grant's funeral, and if the weather should prove hot the probabilities are that there will be plenty of work for it to do. The extremely long march (about eight and a half miles) from City Hall to Claremont, the place of interment, under the blaze of an August sun, would seem to be attended with no little hazard to those participating in the procession.

— PROFESSOR MERKEL, of Königsberg, has been called to the chair at Göttingen, formerly held by Prof. Henle.

# Medical and Surgical Journal.

THURSDAY, AUGUST 6, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.*

## RHEUMATISMS AND PSEUDO RHEUMATISMS.

THE ancients employed the word "rheumatism" (from *rho*, to flow), to indicate diseases in which, according to the humoral theories prevalent, the phlegm, elaborated by the brain, *flowed out* through some of the natural outlets of the body; "*rheuma*" was synonymous with catarrh or fluxion. The word never was used to designate the familiar disease with which it is now associated.

By Hippocrates, Galen, Paulus Ægineta, and their successors, rheumatism and gout were confounded under the one name "arthritis." Neither the chronic deforming variety, now known as nodular rheumatism, nor even acute articular rheumatism was differentiated from gout; with which both seemed to be identified by the general symptomatology and anatomical lesions. The distinction between *arthritis deformans* and *gout* was first clearly formulated by Landré Beauvais, in the year 1800, and since then clinical observations have everywhere established the differential characters.

Baillou (Fr. Baillon) was the first to employ the word "*rheumatisme*" to denote vague pains in external parts, that is, joints and muscles, and to distinguish them from gout with which they had previously been confounded, and Sydenham drew the line between gout and rheumatism more sharply still by calling the former disease "*podagra*."<sup>1</sup>

Gout being excepted, rheumatism became the equivalent of all painful affections of the external parts; these were early distinguished as acute and chronic.

Etiologically, rheumatic diseases were long distinguished as diseases due to cold — diseases à *frigore*. Hence the term rheumatism came to be applied to all diseases so originating, and soon a whole group of phlegmasias, of which cold appeared to be the exciting cause, was enrolled in the class of rheumatisms; there were rheumatic pleurisies, pneumonias and meningites, as there were rheumatic neuralgias and arthralgias due to exposure to cold.

So incongruous and heterogeneous an assemblage of morbid entities could not long be held together by one frail etiological thread, and the domain of rheumatism

became very much restricted when the pathological anatomists removed from it the internal phlegmasias constituting of them essential diseases, and the term was again narrowed to include only morbid states of the external parts; and even here, as Bouchard has shown, the separation of certain synovites, myosites, periostites, left to be included under the head of rheumatism, only certain painful affections of the joints, muscles, aponeurosis and nerves which pathological anatomy was incapable of classifying.

But while pathological anatomy is competent in very many instances to tell what is not rheumatism, it is clear that it has no constant criterion by which it may decide what rheumatism is. Here the criterion must still be sought in clinical experience.

Clinically there is a symptomatic aggregate, familiar to all physicians, sufficiently well defined to constitute a morbid species or type; we allude to acute rheumatism of the joints, or, in more precise language, acute primary febrile polyarthritis. This disease has a definite evolution: is of marked febrile character, though the fever runs no typical course; is multiple and erratic in its joint affections; has certain frequent — especially endocardial and pericardial — visceral complications; the inflammatory swellings accompanying it are of the nature of fluxions, that is, have no tendency to organization or suppuration; it is peculiarly amenable to treatment by certain remedies, as salicylate of sodium (*nutrurum morborum curationes ostendunt*); it is liable to recurrence; it is especially prone to attack youth and early manhood, and to manifest itself after sudden cooling of the body when heated by exertion. Moreover, the malady is of a diathetic character, and has a wide range of morbid affinities. Bouchard, in his remarkable treatise,<sup>2</sup> has shown the bonds of parentage which acute rheumatism has with gout, diabetes, biliary lithiasis, essential asthma, migraine, etc., diseases which he ascribes to retardation of nutrition.

In attributing rheumatism, however, to imperfection and slowing of the nutritive processes, and assigning it a common origin with numerous other dissimilar affections, and even obesity, Bouchard has left the question of pathogeny in great vagueness and uncertainty. We know not what is this specific vice of nutrition, we lack a criterium. To explain the proximate cause, various theories have been proposed; these may be reduced to four: the embolic, parasitic, neurotrophic, and humoral theories.

The first, or embolic theory, has been maintained by Pfeufer, Hueter, and Htop, and presupposes an antecedent endocarditis and the transportation from the diseased valves of minute embolic particles, which obstruct the blood vessels of the affected joint and cause exudation and swelling. This theory is too improbable — not to say inherently absurd — to find many adherents.

The second, or parasitic theory, supported by Klebs, is a modification of the other. Here the emboli are

<sup>1</sup> *Senator in Ziemschen.*

<sup>2</sup> *Maladies par retardement de la nutrition," Paris, 1882.*

not debris from the heart, but are constituted of "figured ferments," micrococci or monads, which get access to the blood through the dilated orifices of the skin, and stuff and obstruct the capillaries of the morbid part. This theory is equally untenable from the present standpoint of medical science. If it should be hereafter proved (which is highly improbable) that rheumatism is an infectious (microbiotic) disease, the finding of the specific bacterium would furnish the missing criterion—would accomplish for rheumatism what Koch's bacillus has done for tuberculosis.

The neurotrophic doctrine is based on the production of arthritis under the influence of lesions of the nervous system. According to this theory, cold acts on the nervous centres and determines modifications in the trophic centres which preside over the joints. We owe to Charcot the first description of the joint diseases which occur in connection with locomotor ataxia. Many years ago a neurotic theory of rheumatism was propounded by the late Professor Mitchell, of Jefferson College, Philadelphia, as Bartholow has recently shown, who ally advocates this theory.

The chemical, or humoral theory refers the joint troubles and constitutional disturbances to an alteration of the fluids of the economy. It is known that the blood of rheumatic fever patients is highly charged with acid, and numerous pathologists, Prout, Fuller, Richardson, Todd, etc., have given cogent reasons for the belief that the peccant matter is lactic acid. There is no doubt that experiments on animals and clinical facts have given support to this view, which, however, still lacks sufficient substantiation. It is probable that the true explanation will yet be found in a combination of the neurotrophic and chemical theories.

The subject of pseudo-rheumatism is one of great interest, but must be reserved for future consideration.

#### AN AMBULANCE CORPS.

THE encampment of the second brigade of Massachusetts militia was made noticeable by the presence of an ambulance corps. The bill which authorized its formation was passed late in the last session of the State legislature, and the appearance of the corps on the field shows great promptness of action on the part of the Surgeon General. Hastily enlisted and brought together for the first time on the camp ground, it would be hardly fair to criticise its action; but even without making such allowances as might justly be claimed, its appearance on the last day of the encampment was highly creditable. It was evidently composed of first-rate material, and its *personnel*—as a matter of fact, it was made up largely of medical students—shows that an interest is taken in the matter by a class of young men who are sure to do good work.

Every day furnished an opportunity for the corps to illustrate its usefulness. The extreme heat of the encampment week was very trying to the men of the brigade. We strongly suspect that errors of diet aided the effects of the sun in some of the men who

succumbed—and though at the camp-ground itself there were no serious cases of sun-stroke, there were several instances of men who were obliged to leave the ranks, and at least one slight accident. All such cases were promptly taken in charge by the ambulance corps and conveyed either to the hospital or to their tents. The march in the city at the close of the encampment was attended by a larger number of cases of prostration from heat than the corps could deal with, but their efficiency on the occasion more than justified their existence.

The men of the corps were armed with stretchers, of which the poles were jointed in the middle. Each man bore one pole, the two pieces and the iron rod which serves to separate the poles being enclosed in a long and tightly fitting canvas sack, and in addition, a haversack which contained one-half of the canvas covering of the stretchers, and various surgical dressings, so that two men carried the complete equipment. The poles in their canvas coverings were borne much after the fashion of a musket, and the appearance of the white canvas against the dark blue of the regulation uniform was very neat and attractive. The Geneva cross on the arm served to distinguish the men when without their equipments. No canteens were furnished this year, which would be a serious omission in an active campaign, but their absence was not an unmixed evil in the present instance.

In addition to the elementary drill of the soldier and the use of their stretchers, the men were exercised in the temporary dressing of fractures with such accidental material as the camp-ground afforded. It seemed to some of the spectators that the time occupied in adjusting the stretchers was longer than ought to be required. Even a few seconds' delay in caring for a wounded man seems long to the bystanders, and if such a criticism was really deserved, further experience in the men and sufficient use of the stretchers to wear off their newness, will obviate the fault. Possibly a stretcher might be devised which would require less time in putting together, though doubtless the subject was well considered before the present form was adopted.

THE JOURNAL gave some months ago the reasons why the creation of such a corps was desirable. We believe its usefulness will justify its existence, and that other States will speedily follow the example of Massachusetts. We are especially pleased to know that an ambulance corps is to attend the long march of General Grant's funeral escort.

#### THE DISCLOSURES CONCERNING PROSTITUTION IN LONDON.

WE confess to having entertained a feeling of strong prejudice against the method adopted by the *Pall Mall Gazette* for influencing the action of the British Parliament upon the Criminal Law Amendment, but conversation with those lately from London, a fuller knowledge of the subject, and a perusal of the complete text

of the report of the *Pall Mall's* secret commission have greatly modified that feeling.

A philanthropist who makes money out of his philanthropy cannot escape, and cannot expect to escape, legitimate suspicions, and the more ghastly the subject the more tainted the profits. At the same time it really seems as if nothing short of the widespread publication of the truth in regard to the traffic in female children in London for purposes of prostitution—and there is every reason to credit the disclosures of the *Pall Mall Gazette*—would have excited public interest and opinion to such a degree as to enforce prompt action by Parliament to afford decent legal protection to young English girls. Moreover, we doubt very much whether this report of the *Pall Mall's* commission is calculated to pauper to immorality. The story it tells is too pitiful.

The prostitution of little children is not a necessary phase of life in a large city. The legal age of consent for girls in England has hitherto been thirteen years. In France, with all her reputed immorality, the law prohibits the admission of young men and of young women to houses of prostitution if under twenty-one years of age.

We have before us a Parliamentary blue book containing a report of a select committee of the House of Lords on the law relating to the protection of young girls, with the proceedings of the committee and minutes of evidence, published in August, 1881, which goes far to sustain the late disclosures. In answer to questions, Mr. Howard Vincent, the Director of Criminal Investigations, stated at that time to this committee that the prostitution of very young children, as of thirteen years of age, was not by any means a novelty; that such prostitution was peculiar to London as compared with towns on the Continent, and that this peculiarity was undoubtedly due to the defect of the English law. He also gave it as his opinion that the prostitution in England was considerably in excess in proportion to the population to the prostitution of other countries.

All this testimony and the facts gathered by this and other committees have been sleeping quietly in print between these official blue covers for a number of years, and yet for one reason or another action upon the law for protecting these miserable children has been delayed. But in three weeks from the beginning of the *Pall Mall* scandal an amendment to the "Criminal Law Bill" providing flogging as a penalty for outraging children was only rejected in the House of Commons by a vote of 129 to 91, and an amendment raising the age of protection of girls from thirteen to sixteen was carried by a vote of 179 to 71.

It would seem as if the law-making body had at length resolved to give young girls something of the protection which the law should throw around them, and that the evil of the scandal will at least be mixed with a large heaven of good.

#### THE BOSTON PENSION BUREAU.

THE Boston Pension Bureau has acquired a good deal of unfortunate notoriety of late years, a notoriety

augmented not a little by the publication last week in the daily press of an open letter under date of July 28th, from Dr. E. N. Whittier, one of the examiners who lately resigned, to Hon. John C. Black, Commissioner of Pensions at Washington. This letter explains the resignations of Drs. Whittier and Gavin from the board of examiners, and gives the history of various discreditable charges, not for the first time heard of, concerning the third member of the Board. Since the resignation of the above-named gentlemen, a third appointee, Dr. Prince, has, after accepting the office, refused to serve, when more fully informed as to the situation. Since then, two physicians, apparently less sensitive, have been found, who are willing to occupy the vacant places and assume the discharge of the duties of pension examiners.

It is, of course, open to each one to decide how much consideration his own personal honor deserves, but this is certain, that, under existing circumstances, it is quite impossible that the Boston Pension Bureau should enjoy the confidence of either the medical or non-medical public. A man with such charges hanging over him as those brought against Dr. Bartlett is unfit to be an active member of such a Board, whether the fault be his misfortune or his fault, and the course adopted by Drs. Whittier, Gavin and Prince will, we think, commend itself to the sympathies and approbation of their professional brethren.

#### MEDICAL NOTES.

— Dr. Aebly, formerly Professor of Anatomy in the University of Berne, and later occupant of the same position at Prague, has recently died.

—The life of the venerable M. Chevreuil, for fifty-five years professor of applied chemistry in the Museum of Natural History in Paris, now in his one hundredth year and still working diligently in his beloved science, presents many interesting and striking facts. Few incidents, however, are more picturesque than his modest reference in the French Academy of Sciences a year or two ago to a communication which he had made to the same society more than seventy years previously. "Moreover, gentlemen," said he, alluding to a statement which he had just made, "the observation is not a new one to me. I had the honor to mention it here, at the meeting of the Academy of Sciences on the tenth of May, 1812."

—The following information in regard to cholera in Spain from March 4, the date of its reappearance, to July 4, is an abstract of the consular reports received by the National Board of Health:—

Province.	Cases.	Deaths.	% Mortality.
Alicante	1,588	646	40.6
Castellon	2,617	1,277	48.8
Cuenca	78	40	51.3
Madrid	1,700	753	59.2
Murcia	6,007	2,319	38.6
Tarazona	31	19	61.2
Ternel	12	5	41.6
Toledo	135	207	45.5
Valencia	11,228	6,851	45.5
Zaragoza	628	280	44.7
Totals.	28,041	12,347	

— Dr. Peters, in the *Medical Record* (May 9th) records a somewhat remarkable instance of the preservative powers of arsenic. The body was that of a person who had died thirty months previously. Upon removal of the coffin-lid no putrefactive odor was perceptible. The skin of the whole body was discolored, but firm and moist. The face was somewhat shrunken, but easily recognizable. The viscera, as well as the muscles of the extremities, were moist, and retained their histological characters and elements. There was not a single perforation from decomposition throughout the alimentary canal. The duodenum, sigmoid flexure, and rectum showed unmistakable signs of inflammation, being much reddened and thickened; but all the other viscera were normal. The gentleman lived for five days after he was poisoned, and the total amount of arsenic found in the body being estimated at five grains.

— Joseph Körösi, of Budapest, in a paper read before the Association of Hygiene, in Berlin, last year, presents some figures regarding the effect of the pecuniary status upon longevity. Excluding deaths in infancy, he finds, taking his observations from a period of eight years, that the rich class had a longevity of 52 years, the middle class of 46 years 1.1 month, the poor class of 41 years 7 months. In the matter of susceptibility to infectious diseases he finds that cholera, small-pox, measles, and typhoid are more prevalent among the poor, and diphtheria, croup, pertussis, and scarlet fever among the well-to-do. Zymotic diseases, as a whole, were 60 per cent more frequent among those living in basements than in higher domiciles. But the increase in fatality in underground tenements applied only to certain diseases, as especially measles and whooping-cough, while diphtheria and scarlet fever were 10 per cent less frequent than in families living above ground.

— A correspondent of the *Lancet* bespeaks the generous interest of the profession on behalf of Dr. Warburg, the discoverer of the tincture which bears his name and which has been found so useful in combating the fevers of tropical countries. Warburg is now upwards of eighty-one years of age and is in straightened circumstances. The correspondent states that some time since he prevailed upon Dr. Warburg to make public the formula of the tincture, which was published in the British journals. But this act put an end to the revenue which had been previously derived from it by the discoverer. Some years ago the government of India granted him £200 pounds for the discovery, but if he is now in want from having relinquished his secret to the world the world should not allow him to suffer therefor.

— Teacher: "So you can't do a simple sum in arithmetic. Now let me explain it to you. Suppose 8 of you have together 48 apples, 32 peaches, and 16 melons, what will each one of you get?"

"Choleric Morbus," replied little Johnny Fizzletop, who is addicted to that malady. — *Texas Siftings*.

## NEW YORK.

— The effect of the recent prolonged period of hot weather is seen in the increased mortality in the city. Up to the time of its advent the death-rate was unusually low for this season of the year; but during the week ending July 18th, there were 1,019 deaths. 613 were among children under five years of age, and 365 of these were due to diarrhœal diseases. Four deaths are directly attributed to the excessive heat, and fifty-four were caused by cerebral and neurotic affections, in which the fatal result was accelerated by the increased temperature. During the week ending July 25th there were 1,094 deaths in the city, an increase of 184 over the corresponding week of last year. Of this number, 479 were of children under one year; 644 of those under two years; and 764 of those under five years. Diarrhœal diseases caused 381 deaths, and of these, 312 were of children under five years. 64 deaths were caused by the heat.

— Dr. Cyrus Edson, Chief of the Second Sanitary Division, on July 30th made a grand raid on the small fruit vendors of the tenement-house district in the Tenth Ward, and confiscated no less than five tons of bad fruit, most of which consisted of pineapples and watermelons. Several other raids have recently been made upon the dealers, in the hope of breaking up this dangerous traffic, but they have had but little effect, as the vendors adopted the practice of keeping spies on the watch, and were generally able to elude the vigilance of the inspectors. On the present occasion, however, a systematic and strategic plan was adopted, which was eminently successful, and the effect of the raid is thus described in one of the daily papers: "The consternation raised in that devoted locality was beyond description. The streets were thronged. Men and women were sitting upon the steps of the houses, in the windows, upon boxes and barrels, and on the sidewalks, and thousands of children swarmed all over the sidewalks and pavements. Dirty little girls, carrying dirty babies almost as large as themselves, were flirting with dirty boys before the saloon doors, young roughs were loafing at the corners, children were playing tag and hide-and-seek about the streets, old women were gossiping on the doorsteps and along the curbstones, and on all the corners the vendors' carts were drawn up and the sale of unwholesome fruit was in progress. When the blue coats of the police-officers were seen on the streets every one realized that a raid was in order, and as every one had some relative in the fruit business, the populace fled to warn its friends, and then there was a chorus of polyglot profanity — Hebrew, Italian, German, French, Alsacian, Chinese, and all the various dialects thereof, arose in one jumbled but pathetic protest. The vendors, pushing their carts before them, ran panic-stricken through the crowded thoroughfares, all centering unwittingly toward Hester and Essex Streets, and the eight divisions of police, marching in from eight directions were followed by eight howling mobs heap ing imprecations upon them."

—The marble statue by Mr. Boehm, erected by the admirers of Mr. Charles Darwin in his honor, has been completed and placed in the main hall of the building containing the natural history collections of the British Museum at South Kensington. Professor Huxley delivered the address at its inauguration. It stands at the first landing of the great staircase, says the *London Times*, "as though to welcome all coming generations of students as they enter the door of the building in which so many of the materials of their work are gathered together." So far as was possible, Mr. Boehm has rendered the very features and character of his subject; and all Mr. Darwin's friends agree that a likeness more characteristic, whether in face or attitude, could hardly have been produced, even by a sculptor who had been intimately acquainted with him in his lifetime. The head is full of dignity: the great brow, the flowing beard, the expression, full at once of intense thought and human feeling, have been caught and fixed in the marble."

### Miscellany.

#### THE STRAIN OF MADNESS IN VICTOR HUGO.

THE alliance of madness with genius, so often noted, seems to have had a fresh exemplification in the case of Victor Hugo, as is pointed out in the *Medical Times*:—

"His uncle died insane; his brother, Charles Hugo, who at an early age gave promise of great literary talent, became insane before twenty, and spent the latter part of his years in a hopeless state of dementia; and one of the poet's daughters, still living, is the inmate of a 'maison de santé.' That in a family thus tainted with insanity a man of immense genius should arise is only another instance of that close hereditary connection between mental disease and highly intellectual powers, which Moreau de Tours so forcibly pointed out in his celebrated book *La Psychologie Morbide*; but any impartial reader will find in many of Hugo's best writings a large number of passages which could only have been conceived by a diseased imagination, and which bear the indelible stamp of madness. In this respect the French poet widely differs from his great prototype, Shakespeare, who in the wildest flights of his poetical phantasy still remains faithful to sound common sense. The mind of Shakespeare was evidently a healthy one; that of Hugo was not; and if some future Plutarch attempts to strike a parallel between these two great literary giants, he will do well to keep this fundamental difference in view. It may seem ambitious to compare Hugo to Shakespeare, but in this city and at the present day most people seem inclined to place the modern poet above the older bard, an exaggeration which time will doubtless dispel. Yet, as regards the conduct of his private affairs, no man could excel Victor Hugo in that shrewdness which persons not quite right about the head so often exhibit. No banker could more carefully have managed his fortune, no politician could more tenderly have nursed his popularity; and the man who left a fortune of more than two hundred thousand pounds sterling was the idol of a jealous democracy, while the politician

who played at fast and loose with all parties was buried in the midst of universal applause. Such an instance of great 'wit to madness near allied' the annals of the civilized world have never hitherto placed on record for the edification of posterity."

#### WATER-PURIFICATION OF SEWAGE.

THE contamination by sewage and other foul matter of the sources of water supply of many of our large cities, despite all efforts of municipal authorities to prevent it, is justly a source of apprehension to the hygienist as well as of a rising of the gorge to all who witness the pollution. Some crumbs of comfort, however, may be gained from the statements in the August number of the *Popular Science Monthly*, regarding the oxidizing power of water. The important part played by water in the oxidation of sewage has been tested by experiment, and may be accounted for by the quantity of free oxygen that water usually contains. The quantity that may be dissolved is increased with reduction of the temperature. At the summer temperature of 70° F., water contains 1.8 cubic inch, and at the winter temperature of 45°, 2.2 cubic inches, of oxygen per gallon, which is equivalent to four or five cubic inches per foot. From calculations based upon these data, it will be seen that at a temperature of 70° there are 2.58 tons, and at the temperature of 45°, 3.16 tons, of oxygen in every 10,000,000 cubic feet of water. This shows a difference of more than half a ton per cubic foot between these two temperatures. It has been calculated that if a volume of water containing thirty-five per cent of sewage-matter be allowed to flow for one mile, exposed to the air, the whole of the sewage would become oxidized. It has also been estimated, by experiment, that a closed vessel containing water, with five per cent of sewage, gives only thirty-two per cent of aeration on the fourth day, as compared with eighty-four per cent on the day when it is introduced into the vessel. The results of these experiments tend to show that, although the self-purifying power of the water of the river is sometimes overtaxed, it still retains the power of oxidizing sewage-matter; but the question as to whether it has the power of freeing itself from living bacteria still remain to be solved.

#### MICROBES IN SEWAGE IRRIGATION.

THE *Popular Science News*, August, 1885, refers to a curious experiment, shown a year or two ago, in which a long glass tube was filled with earth, and sewage poured in at the upper end. If the tube was long enough, perhaps six or eight feet, the liquid issued from the bottom clear and pure; its dissolved and suspended organic matters having been oxidized by the soil. If, however, before pouring in the sewage, a little dilute chloroform was allowed to filter through the earth, sewage subsequently applied passed through the tube without change; the oxidizing action of the soil being completely suspended. After some hours or days, the soil regained its oxidizing quality. This experiment was believed to show that the oxidation of organic matters in sewage was something more than a chemical reaction, and that it depended, at least to a certain extent, on the presence of small living organisms, whose activity could be temporarily suspended by an anæsthetic, and with it the oxidation of the sewage. This theory has now been confirmed by

additional observations; and the little creature which converts into fixed and harmless salts the putrefying impurities of such sewage as it can reach, is believed to be a micrococcus somewhat resembling the yeast-plant. Many and varied tests have been made to determine the conditions under which the disinfecting microbe lives and acts, and a good deal has been learned about its habits. It is found that it flourishes best, and is most efficient, at a temperature of about ninety-eight degrees Fahrenheit, nearly the temperature of the blood. At higher or lower temperatures its action becomes more feeble, and ceases altogether near the freezing-point, or above one hundred and thirty degrees. Experiments to show its distribution in a clay soil prove that it is most abundant in the upper six inches, but is found to a depth of a foot and a half. Below that depth it cannot live, and soil taken more than eighteen inches below the surface has hitherto always failed to induce any change in nitrogenous solutions to which it was applied. These experiments cast a great deal of light upon many questions of sewage disposal by subsoil or surface irrigation; and further tests, made with some reference to this, would be easily made and extremely valuable. It is found, for instance, that nitrogenous solutions, in order to be acted upon by the oxidizing ferment, must be alkaline; acid liquids remaining unaffected. This observation shows at once, that, where sewage is to be purified by irrigation, chemical wastes must be kept out of the drains. Normal house sewage is generally slightly alkaline, and in good condition for conversion; but the admission of the acid or poisonous wastes from a dye-house, metal-working shop, or manufactory of any other kind, might render the sewage of a whole town incapable of purification.

## Correspondence.

### ANATOMY AT THE HARVARD MEDICAL SCHOOL.

MR. EDITOR.—Dr. Monks' thoughtful paper on the teaching of anatomy in England and America, which appeared in your last number, opens a question of great interest and importance. As Dr. Monks points out, it is very difficult to compare the American system with the English, owing to the great variations of standard in American schools. While thanking him for the handsome compliment which he pays to the anatomical department at Harvard, I shall assume that his remarks apply chiefly to this school. There is internal evidence of this in his paper. I am far, however, from resenting such criticism. Medical education is to some extent a trust, and the profession, as the only part of the community competent to do so, has the right to inquire how it is administered. Further, a professor is naturally held accountable for the success of his department, and it is but just that he should have an opportunity of stating to what extent he is responsible for its shortcomings by which his reputation must suffer.

Dr. Monks' chief proposition that anatomy is more thoroughly taught and highly esteemed in England than in America, in general (and I will add at Harvard in particular), is, I think, undoubtedly true. The higher esteem is the result of the better teaching, and one reason why English clinical teachers insist more on anatomical points, is that their own training has rendered them more competent to do so. Dr. Monks' criticisms on our system are in the main very true, and his suggestions for improving it theoretically good, though not without practical difficulties. He hardly does us justice, however, in his remarks on the nature of the examination questions. He says that the

questions are never very practical and all not so selected as to draw out the real practical knowledge of the student. As far as this applies to the Harvard examinations in topographical anatomy, it is, I think, unfounded. The papers are published in the catalog, and every one can judge for himself. I will venture, however, to give the paper of June, 1883, as a specimen.

1. Give the relations of the following parts in the back to the spines of the vertebrae or to the ribs: (1) the upper and lower limits of the oesophagus; (2) of the pleura; (3) of the lungs; (4) of the scapula; (5) the bifurcation of the trachea; (6) the end of the arch of the aorta, its passage through the diaphragm, its bifurcation; (7) the end of the spinal cord and the points of origin of the plexuses.
2. The position and relations of the parotid gland, and the structures within it.
3. Describe a section through the middle of the upper arm. (This may be answered by a diagram with proper explanations.)
4. Describe the structures and their relations in each layer of the anterior femoral region between Ponsart's ligament and a transverse line at the apex of Scarpa's triangle, as deep as the floor of the triangle inclusive.
5. What are the relations of the patella to the bones in the various positions of the knee-joint.

A much more serious criticism is that on the time of the examination. At Harvard, the chief examination, that on descriptive anatomy, occurs at the end of the first year. Three hours are allowed. That on topographical anatomy, on which there is but one lecture a week, comes at the end of the second year and occupies one hour and a half. This is, in my opinion, the radical defect in the anatomical course at Harvard. When the graded course was adopted in 1871, anatomy was made a first year study. The results have been most lamentable. The details of anatomy can be mastered only by frequent reviews. Much of anatomy is as meaningless to the beginner as the multiplication-table is to a child. At least a second course is needed for the student to relearn the details he has forgotten, and to perceive the importance and interest of much that at first was simply wearisome. Moreover, his clinical studies lead him to study medicine from an anatomical standpoint, and anatomy from a clinical one, but unfortunately, in the new system, his anatomical studies were finished before his clinical ones began. The University of Pennsylvania and the College of Physicians and Surgeons of New York, have been wiser in this respect. Five or six years ago the committee of the Overseers reported that the course was insufficient, and that on topographical anatomy was added. This was an improvement; and the efficiency of the department has of late been further increased by the great devotion of the demonstrator and his assistants. Nevertheless, the radical defect still remains that the chief examination comes at the end of the first year, before the students can possibly have acquired a satisfactory knowledge of anatomy before they have been able to grasp its bearings and usually before they have completed their dissection. I fear it is a fact that the Harvard graduate is not only far behind his English cousins in anatomical knowledge, but behind the graduates of several schools in his own country. I deplore this, but cannot remedy it. Now that Dr. Monks has brought the matter before the profession, I hope that those who have opportunities of judging of the correctness of my apprehensions, will speak without fear or favor.

THOMAS DWIGHT, M.D.

### THE INTERNATIONAL MEDICAL CONGRESS AND THE AMERICAN MEDICAL ASSOCIATION.

MR. EDITOR.—Having been a subscriber to and a reader of the JOURNAL for more than twenty-five consecutive years, I take the liberty to offer some thoughts for publication on the position taken by many men eminent in the profession, touching the International Medical Congress and the action of the American Medical Association as connected with and making arrangements for it. Assuming that a Congress is desirable and will conduce to the advancement of true medical science in the American profession we come legitimately to the question of the proper body or society to extend the invitation to and make the necessary arrangements for the congress, and the discussions thus far have not questioned or denied that the

American Association was the fitting power to assume these duties. The manner of discharging the duty of making the arrangements seems to be the *casus belli* with both friends and foes. That in the association was the proper power to appoint the original committee of eight is unquestioned, and with this conception necessarily comes the power to enlarge or change the committee. The charge is unwise and hurtful in so doing—thus rendering a successful congress, if not impossible, surely very improbable.

Of the action of the first committee in its appointments or the committee as enlarged I do not propose to speak at length, remarking only that doubtless both in some respects are open to just criticism. If my understanding of the matter is correct the subject at issue is the question of ethics. This being admitted we come legitimately to the consideration of the two ethical factions of the present time, the old, as represented by the American Association, its members and supporters; the new by the New York State Medical Society, its members and adherents. The origin of the antagonism was, I think, in this wise: a number of members of the New York State Society—largely resident in the city—claimed that the ethics of the National Association were illiberal and unworthy of the advanced medical thought of the times, and by their efforts succeeded in putting the State Society in antagonism with the American Association, whose friends at the next annual meeting of the State Society endeavored to restore it to its loyalty but did not succeed. In the discussion of the question many, and notably those of the new code, evinced that heated blood was cursing their veins by applying the epithet of old feyism to the National Society and calling for evidence of its having done any advanced scientific work. And here it seems in place to ask what constitutes the ethics of the National Association; I understand it is in brief this: it welcomes and admits all honorable medical men who do not practice, advocate, or believe any special dogma in medicine. Can it be more liberal and be worthy the name of code? Granting it did or does need changing for the better advancement of scientific interests of the profession, could not these gentlemen, very many possessing acknowledged high attainments, have very much more effectually aided the advancement of the best interests of the American profession by using their acknowledged power in endeavors to correct the faults alleged rather than in antagonizing the Society, thus detracting from its power for reform. Being a believer in the benefits derived from fraternal association and the necessity for a declaration of and adherence to principles held in common by members of societies; and also a believer in the benefits arising from an educated consistent conservatism, with due respect to opinions as set forth by action, I opine they could. But believing their course honestly taken—and, if you please, conceding it correct—while admiring their genius, and not forgetting that this same genius may, to a certain extent, render them a law unto themselves, we are forced to the conclusion, if we adopt old and established rules of honor, propriety, and self-respect, that to fill positions coming directly from an organized body for whose principles and methods they have so little respect, necessitates the adoption of ethics of honor and self-respect fully as liberal and containing as largely the personal element as is found in the latest revision of the medical code.

Experience has demonstrated the fact that in association men engaged in a common occupation or profession are benefited, even should the rules adopted for their government be not absolutely perfect. Concessions are a necessity in all human association. Very truly yours,

C. C. STARY, D.D., M.D.

[The code-question should really have nothing to do with an International Congress. Apart from this it is very well understood that the disturbance at New Orleans was incited by disappointed personal ambitions. The code and geographical distribution have been used to arouse opposition to the arrangements of the first committee. Etc.]

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 25, 1885, TO JULY 31, 1885.

APPEL, A. H., captain and assistant surgeon. Ordered for duty with United States troops, forming portion of guard of honor over remains of ex-President General Grant, at Mt. McGregor, N. Y. S. O. 36, Division Atlantic, July 23, 1885.

BILL, Jos. H., major and surgeon, United States Army. Died at Yonkers, N. Y., July 21, 1885.

DE WITT, CALVIN, captain and assistant surgeon. Promoted to major and surgeon, vice Bill, deceased, to take effect from July 21, 1885.

EBERT, R. G., captain and assistant surgeon. From Department of Columbia to Department of East. S. O. 170, A. G. O., July 27, 1885.

GERARD, A. C., captain and assistant surgeon. From Department of East to Department of Columbia.

MCDONGALL, CHARLES, lieutenant-colonel, United States Army (retired). Died at Fairfield, Va., July 25, 1885.

IVES, FRANCIS J., Appointed assistant surgeon with rank of first lieutenant, to rank as such from July 25, 1885.

GORIAS, WILLIAM C., captain and assistant surgeon. Granted leave of absence for two months, to take effect about August 10, 1885. S. O. 169, A. G. O., July 25, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDED AUGUST 1, 1885.

AMES, R. P. M., passed assistant surgeon. Granted leave of absence for thirty days, July 27, 1885.

FESSENDEN, S. D., surgeon. Leave of absence extended eight days on account of sickness, July 20, 1885. Extended ten days on account of sickness, July 27, 1885.

GODFREY, JOHN, surgeon. Granted leave of absence for thirty days, July 29, 1885.

IRWIN, FAIRFAX, passed assistant surgeon. Granted leave of absence for ten days, July 13, 1885. To inspect unserviceable property at St. Louis, Mo., July 15, 1885. To proceed to Richmond, Va., and Wilmington, N. C., as inspector, July 28, 1885.

#### SOCIETY NOTICES.

ILLINOIS STATE BOARD OF HEALTH REGISTER OF PHYSICIANS AND MIDWIVES.—The Illinois State Board of Health is now engaged in revising its "Register of Physicians and Midwives." Any notification of changes, omissions, or errors will be regarded as a favor; as the Board wishes to make the forthcoming register as correct as possible. Address, "Secretary State Board of Health, Springfield, Ill."

#### APPOINTMENT.

DR. THOMAS DWIGHT has been appointed by Mayor O'Brien, to be a member of the Board of Directors of Public Institutions, in place of Mr. A. T. Whiting, resigned to accept a place on the newly-organized Board of Police Commissioners.

CARNEY HOSPITAL.—The following appointments have been recently made: Surgeon, W. A. Dunn, M.D.; Surgeons to Outpatients, G. H. Monks, M. D., H. W. Cushing, M.D.

#### ERRATA.

PAGE 115, July 30th, in second column, seventh line, *storm* signals not *shown*. Night storm signal is *red*.

## THE CAUSES AND PREVENTION OF INSANITY.

BEING THE SUBSTANCE OF AN ADDRESS DELIVERED AT THE  
OPENING OF THE SECTION OF PSYCHOLOGY,

At the Annual Meeting of the British Medical Association held  
in Cardiff, July, 1885.

By D. VELLOWLES, M. D.,

Physician-Superintendent of the Glasgow Royal Asylum; and  
Lecturer on Insanity in the University of Glasgow.

My first duty is to acknowledge the great honor done me by the Council of the Association in inviting me to preside over this Section, an honor which I very highly appreciate, and which is doubly welcome because our meeting is held in the county whose asylum I organized and opened twenty years ago, and in whose service I spent eleven of the best years of my life.

At our last annual meeting at Belfast, the subject of the presidential address was the relation of our speciality to the other branches of medicine. To-day, I invite your attention to our relation and duty to the public, as regards the causation and prevention of insanity. This is a practical rather than a pathological aspect of our subject, but its extreme importance must atone for the want of purely scientific interest.

During the dark period when insanity was at once the reproach of medicine and the horror of the public, the mere suggestion that the nervous system required wise and watchful care was resented as an insult, because it seemed to impute a liability to mental disorder. Now that insanity is no longer deemed either a crime or a disgrace, there is some hope that the counsels and warnings of the physician may receive greater attention.

The causes and prevention of insanity may well be considered together, for prevention can be intelligent and effective only in proportion as the causes are accurately ascertained and wisely avoided.

The causes of mental disorder group themselves at once into two categories; those arising from conditions in the life-history of the individual, and those entailed upon him by ancestral inheritance. It is too true that both kinds of causes often co-exist, and that the immediate or personal cause is potent only because it has awakened and developed inherited weakness. Still, there are causes so directly personal to the individual, that they must be regarded as sole and sufficient, irrespective of inheritance. The chief causes of this class are brain-injury, brain-exhaustion, brain-anæmia, brain-irritation due to disease in other organs, and organic changes in the brain itself. From such causes any brain may suffer, and they may induce insanity in persons wholly free from hereditary neuroses.

*Brain-injury* is a cause often assigned by friends, without sufficient grounds, as the history of a blow or fall seems to them to remove all suspicion of hereditaryness.

Undoubtedly, mental peculiarities, or an entire change of character sometimes follow a blow which has left no outward sign; and it is equally certain that the commencement of organic disease, or of the chronic changes of general paralysis, may date from such an injury.

The mischief produced may be out of all proportion to the apparent severity of the blow, and therefore such injury should never be lightly regarded. On the other hand, it is a mere shot in the dark to assign as

the cause of insanity a head-injury sustained some years previously, if it have meanwhile given rise to neither local irritation nor general symptoms. Distance magnifies the gravity of the injury, and friends unconsciously mislead the physicians and themselves in their desire to demonstrate the accidental origin of the disorder.

*Brain-exhaustion* may follow from continual overwork or incessant worry, if the brain have been denied due rest and sleep. The student, the politician, and the merchant, may alike be victims of brain-exhaustion, in their undue pursuit of knowledge, influence, or wealth.

This is too high a price to pay for anything on earth. Besides, such overwork often defeats its end, for the work of a wearied brain is never the best work of which it is capable. Our powers will bear spurring for a time; but there is a limit, beyond which the effort is fatally exhausting, while the result is woefully inadequate.

Reason and life are often sacrificed in the rush of our high pressure civilization; and the influence of this civilization, with its terrible extremes of reckless luxury and woeful want, on the national brain and the national character, is a momentous question. Assuredly it is our province and duty to proclaim that such flagrant violation of the laws of brain-health cannot be perpetrated with impunity, but must entail direful results.

Far commoner than exhaustion from overwork, and far more potent as a cause of insanity, is the irritation and exhaustion produced by excesses in the two most frequent forms of alcoholic and sexual dissipation. The ruin of brain wrought by intemperance, whether in its sudden and fiercer forms, or in the chronic delusional conditions to which they tend, is too familiar. Too familiar, also, is the drink-crave, to gratify which, even for a moment, love and honor and truth and duty are all forgotten. This malady, which some would vainly persuade us is but vulgar vice, is often an inherited neurosis, and then belongs to the second category of causes; but often, too, it is the outcome of habitual indulgence, and thus ranks as a personal cause.

Brain exhaustion from sexual excesses, or from self-pollution, is another fruitful cause of insanity, and it is wholly a false delicacy which hesitates to expose this degrading evil. We know too well how one purient boy can pollute a whole school with the vice of self-abuse, though we can never know or measure the ruin he may have wrought. We are too often sadly certain that like practices exist in the sex where we expect only purity and innocence, and that they produce sorrowful results in all the protean forms of nerve instability. We know, too, how the marriage relationship can be degraded into an excuse for unbridled indulgence, and that such folly or ignorance may wreck the strongest brain.

Society needs plain words about these things, and we fail in our duty if we do not speak them. Especially do we need to impress on parents the duty of wisely informing their children, lest ignorance, or, still worse, knowledge wrongly sought for, prove fruitful of evil.

*Brain-starvation*, whether the anæmia result from malnutrition or from undue waste, may give rise to mental disturbance, which is, happily, curable by the removal of its cause.

*Brain-irritation*, due to disease in other organs, may

produce insanity, either through nervous sympathy or through disturbance of the quality and regularity of the blood-supply.

Lastly, among the personal causes, *organic changes in the brain itself*, of whatever nature, and however produced, may develop insanity, whose symptoms, when thus arising, we can, at best, only try to mitigate.

It may seem as if a large group of personal causes had been omitted. Emotional causes, such as terror, anxiety, and disappointment, seem at first to be purely personal, and therefore to belong to this category. Doubtless, this view is sometimes correct; but in the majority of cases, these extreme emotions are essentially manifestations of an inherited nervous temperament, without which the insanity would never have occurred. The joys and sorrows of humanity are too familiar and inevitable to develop insanity, except in brains predisposed to it.

*An inherited predisposition to insanity* is assuredly the most potent of all the causes which produce it. Every attack of insanity, however produced, certainly creates a liability to its return; and this acquired tendency is at least as grave a fact in the history of the individual as a predisposition inherited from his ancestors. How this predisposition, whether inherited or acquired, can be managed and modified, is the question now before us; and we could scarcely have under consideration a more important or a more practical subject.

First, and chiefly, we can certainly declare that this predisposition is not a mysterious and fatal doom, haunting and dogging its victim, and sure one day to overtake and overwhelm him. It is a purely physical condition, and loses half its horror when this is realized. We cannot, it is true, fully understand the pathology of nerve-instability; but we know that insanity is only one of its many manifestations, and that it may equally reveal itself in paralysis, epilepsy, and neuralgia, in asthma, diabetes, and hysteria, and also, beyond doubt, in certain types of drunkenness, of crime, and of genius.

The subject of this predisposition should not pretend to ignore it, as though it was a nameless horror or a secret disgrace. The fancied disgrace is a wretched relic of the time when an insane man was deemed something lower than a brute, and was treated accordingly. The civil and social consequences of insanity are doubtless grave, but it no more implies disgrace than any other physical illness. We are all handicapped, in some way or other, for the race of life, and much of our success depends on recognizing this from the first and running accordingly.

Supposing the heir to such an inheritance frankly recognizes the fact, how shall we counsel him to avert the malady, and how should his life be ordered so as to prevent its development and transmission? It need scarcely be premised that no organ can be in vigorous health unless this be the condition of the organism. It is an axiom in all special treatment, that the general health must be maintained at the highest possible standard.

The first condition of brain-health, as it is the first condition of the health of every organ, is due and suitable exercise. If the brain work be unduly prolonged or unduly severe, injury must follow. Therefore our imagined patient must not pore unrelentingly over the merchant's ledger, nor burn the midnight oil in explor-

ing the arcana of science, and we must absolutely debar him from the rivalries of politics and the excitement of the Stock Exchange. Unwonted responsibility, or undue worry, tax him injuriously, and he should work within accustomed limits, and along familiar grooves, which habit has made smooth. His ambition must be controlled by prudence, he should be a servant rather than a master, and he should choose the calm and even tenor of a country life, rather than mix in the rush and excitement of a great city.

Relaxation, the exercise to which inclination rather than duty prompts, is essential to him even if he be so fortunate as to find his daily work a daily pleasure. The relaxation should be something unlike his regular work. If possible, it should be in the open air, and occupy both body and mind. He may, with advantage, become so addicted to it that his friends will smilingly call it his hobby, and he will be wise if he choose as his hobby — though, indeed, hobbies are rather adopted by instinct, than selected by deliberate choice — something independent of the changing seasons, and which will not fail him in feeble health or declining years. The relaxation should include, in most cases, frequent short absences from the familiar surroundings and duties of home. An entire change, bringing new scenes, new faces, and perhaps a new language, has a wonderfully renovating power. It makes home more welcome, and familiar duties less irksome if we leave them for a time.

Exercise, whether for duty or for pleasure, implies and procures rest; and for the subject of nerve-instability, sufficient and complete rest is indispensable. His rest should not be mere languid laziness, but genuine nerve-repose in sleep. If he can dine early, and sleep an hour thereafter, he will do most wisely; and his head should be on the nightly pillow at least an hour before midnight. In the evening hours, he should avoid subjects likely to engross or agitate, that sleep be not hindered; or he should change the current of his thoughts before retiring, by such distraction as a book or a newspaper affords. I know an eminent asylum-physician who habitually took the *Times* to bed, and found a soporific in its columns.

Some men are said to have possessed the invaluable faculty of sleeping at will amid any circumstances and surroundings. The man who could discover this secret, and confer the gift on his fellows, would be one of the greatest of benefactors of his race. To seek sleep by the use of hypnotic drugs is rarely wise. It is often but combating the symptoms while the cause continues, and is frequently both futile and injurious.

But exercise, relaxation, and rest, while essential to brain-health, are not everything. Our emotions and affections are the mightiest factors in our lives, and they afford a vast field for the manifestations of nerve-instability. It is in the regulation of our moral nature, and in controlling our fancies, impulses, and passions, by reason and duty, that the hardest battle must be fought.

From whom are the ranks of the insane mainly recruited? Certainly from the men and women whose minds and hearts are untrained and ill-balanced, who are swayed by caprice or passion, who are fretful at every difficulty and envious of their neighbors' good, who are incapable of sustained effort or daily self-denial, and whose lives are thus ill-regulated, changeable and useless. The access of insanity is often but

the ultimate and utter wreck of a vessel without a helm, which has already been many a time damaged by storms of passion on the quicksands of indulgence.

Daily self-control, and wise moderation in all things, should characterize every one; but they are specially required in one predisposed to insanity, and they must be earnestly cultivated by him till they acquire the blessed ease of habit, and are practised without an effort. An education which has failed to educe or impart these qualities has truly failed, and a life which has failed to teach them has been essentially a life of failure. "Greater is he that ruleth his spirit than he that taketh a city." Too often such qualities and lives are inherited, but too often they are created or aggravated by faulty education and foolish training. To correct the evil, and to foster the good, nothing is so potent as wise training in early years; but it is impossible to speak of education in relation to brain health without indignation and sorrow; the evils are so great, the remedy so difficult.

It seems impossible, in any national system of education, to do otherwise than have certain standards of knowledge for certain ages of pupils; yet it is utterly unphysiological to assume that all brains are alike and can acquire with equal ease; and unless the rigidity of the system be modified by the wise discretion of the teacher, great hardship and injury must be inflicted. It is, however, among the better classes that the evils of faulty upbringing are most noticeable and mischievous. The boys get early into harness of some sort for the work of life, and find their lessons, and their level, in the rough school of experience; but the girls want this corrective, and it is the future wives and mothers who are chiefly injured. All sorts of knowledge are indiscriminately stuffed into the head, irrespectively of selection, assimilation, or enjoyment; the accomplishments which society is supposed to demand, are added, regardless of aptitude or inclination; what is showy and ornamental is encouraged, what is sensible and useful is forgotten; and when the young lady is "finished," her character is too often allowed to form itself amid a round of frivolous occupations and yet more frivolous amusements. Marriage finds her sadly wanting, alike as a companion to her husband, as the head of a household, or as the mother of children; and when, happily for the husband, she misses a dignity for which she is unfit, her wretched training makes her a sourd, fretful, resourceless, disappointed being. While we rejoice in the multitude of homes where it is otherwise, we all know that in many cases this sad impeachment is too well founded.

Right feeling and conduct towards others are as needful as due control over our own impulses and desires, if life is to be sane and happy. No man liveth to himself; he could not, if he would; he would be a miserable wretch if he tried. It is needful, therefore, that our patient should have interests beyond himself, and should not live for merely personal ends. Such ends must by-and-by seem meagre to us all, and he of all men needs to lighten his daily life by the feeling that it blesses others as well as himself.

The question of marriage is a grave one in these cases. It is a welcome sign of growing intelligence in such matters, that this question is being put to us with increasing frequency. If the predisposition be but slight, and of remote origin, it seems hard to forbid marriage; but we can urge that the partner selected should be of calm and well balanced mind, and

free from all nerve-proclivities. Unfortunately, excitable, unstable folks have an attraction for each other as remarkable as it is unwise. If the tendency be marked, the prohibition should be absolute. It is far better to endure isolation, and to miss the comfort and solace of married life than to bring sorrow on others, and unknown ill's upon off-spring. To choose a partner beyond the age of child-bearing is one way out of the difficulty; but choice in these things is guided by feeling rather than by judgment, and love is so blind and persistent, that our wisest councils are often disregarded.

The chiefest safeguard comes last, for I should be guilty of a fatal omission, and false to my deepest convictions, if I did not regard as the chiefest, faith in the unseen God. The relation of religion to insanity is often misunderstood. When the gloom of a melancholic takes a religious type, what is but a symptom is often regarded as the cause; the ease is called religious insanity, and religion is supposed to have produced the disorder. It would be as accurate to regard the imaginary ailment of a hypochondriac as the cause of his condition. Cases certainly do occur in which true religious anxiety has produced insanity; and it would be strange indeed if the subject which is greatest of all, and which stirs the mind most deeply, did not sometimes overwhelm it; but too often this sad result has followed from views of religious truths so false and distorted as to be a libel upon its name. There is no security for conduct, no strength for duty, no support in sorrow to be compared to that which true religion affords. Tempests of trouble will not overwhelm the man who endures as seeing Him who is invisible.

#### DIAGNOSIS AND TREATMENT OF POSTERIOR POSITIONS OF THE OCCIPUT.\*

BY WILLIAM L. RICHARDSON, M.D., OF BOSTON.

Called to a case of labor the physician promptly responds. According to the account, given by an intelligent nurse, the labor has been going on two or three hours. The patient's condition, both mental and physical, is good. A vaginal examination discovers the os uteri to be one-third dilated, the child's head presenting. Having assured all the interested parties of the perfectly satisfactory condition of the situation, the doctor hastens away to complete the work of the day, so as to be on hand when his services shall be required. A few hours later he finds the os uteri fully dilated, the head somewhat descended, although not quite so far as he had anticipated, and, again congratulating the patient and her friends on the favorable progress of the case, he once more hastens away to make the remaining one or two visits, possibly revolving in his mind, however, the conscious surprise that he experienced in not finding the head further advanced. Returning in an hour, his work for the day done, the head is found to be a trifle lower, the pains excellent, but the woman somewhat tired. Realizing that the end is not far off he awaits the termination of the labor, which is now, in his opinion, close at hand. Time passes; the pains are all that could be desired, but the child is not born. Flattering himself that the head is lower, at least it ought to be

\* Read before the Massachusetts Medical Society, June 10, 1885, and recommended for publication by the Society.

and he hopes that it is, he waits. One, two, hours go by; the woman, like the doctor, becomes impatient, but there is no progress, except what the doctor tries hard to imagine. The patient's pulse, as well as her mental condition, is beginning to show the effect of the labor. It is evident that something must be done, and, all that is needed is a little help, the aid of forceps is invoked. Assuring the patient and her friends that the operation really amounts to nothing and that in a few moments, without further suffering, the child will be born, the patient is etherized, the forceps are applied, traction is exerted and the forceps begin to slip. Surprised, disappointed, wondering and with some misgivings, the forceps are reapplied only to slip again; the head remains where it was. A more careful examination is now made, but no light is thrown on the problem, and the puzzled attendant asks for the assistance of a friendly professional brother. He arrives, but somehow the forceps again fail to work. The case begins to look serious. At length, after alternate pulling on the handles and readjusting of the blades, the child is delivered still-born; the perineum is sewed up and the doctors retire homeward, each explaining to the other what the trouble was, and, at the next meeting of the local medical society, the doctor reports the case as one of difficult forceps, owing to a slight, though undescribed, pelvic deformity. The nurse, if very intelligent and observing, wonders to herself why the face, when it escaped from the vulva, looked forward instead of backward, and the youngest member of the local society, fresh from the medical school, suggests that the trouble might have been due to an unrecognized posterior position of the occiput, and consequently a wrong application of the forceps; a suggestion received with that silent smile of experience which at once sets the young man to thinking, and possibly also some of the older members of the society.

The above sketch is the clinical history of not a small number of obstetric cases; the above undescribed but assumed pelvic deformity the cause of a fair proportion of still-born children.

Two years ago, asked by the students of the Harvard Medical School to lecture on the mistake which, when called in consultation, I most frequently saw made by physicians, I spoke on the diagnosis and treatment of this class of cases. Asked by the committee in charge to prepare something for this annual meeting of the Massachusetts Medical Society, I could think of no more practical subject, and therefore offer the following brief paper on the Diagnosis and Treatment of Posterior Positions of the Occiput, occurring in a normal pelvis and with a normal fetus at full term.

The careful obstetrician is one who recognizes that for an intelligent attendant on a case of labor a knowledge of the fetal position is just as important as a correct diagnosis of the presentation. As a rule, however, practitioners usually content themselves with making out the presentation, and, having ascertained themselves that the head is presenting, consider the position a matter of minor importance, knowing that cephalic presentations usually come out all right. Now, as a matter of fact, it is in these head presentations that a comparatively slight deviation from the usual position can occasion more difficulty than in any other, for the reason that the deviation is usually unrecognized and the assistance often rendered, when

the case does not progress as the practitioner had anticipated, is consequently unscientific and not unfrequently precisely the reverse of that which the condition demands.

The neglect to make out the position until some unexpected and unexplained delay renders such knowledge imperative, allows the formation of a caput succedaneum. This of itself often renders any attempt to make out the diagnosis per vaginam a matter of considerable difficulty; while the oedema of the vagina in advance of the presenting part only adds to the obscurity of the problem.

The diagnosis of a position would be rendered much easier if the practitioner would avail himself of the great advantage to be gained by the use of external palpation.

Fourteen years ago (1871) I read at the annual meeting of this Society a paper on the use of External Manipulation in Obstetric Practice, showing with what ease the presentation could be made out by this method of examination. The paper contained nothing original, being simply a statement of the teaching in Vienna at that time. My attention was subsequently called to a paper<sup>1</sup> read in 1869 by Dr. J. T. Whitaker, before the Cincinnati Academy of Medicine, on "The Examination by Palpation of the Pregnant Abdomen," which was also a *résumé* of the practice in Germany. In 1872, Dr. J. R. Chadwick published<sup>2</sup> a more detailed account of the continental methods of making external examinations. In 1873, and again in 1875, Dr. Frank C. Wilson published<sup>3</sup> papers on "Fetal Physical Diagnosis," with, however, special reference to the value of auscultation. In 1879, Dr. Paul F. Munde published<sup>4</sup> an admirable article on the "Diagnosis and Treatment of Obstetric Cases by External Manipulation." None of these writings, however, contained any special directions as to the method of differentiating the posterior from the anterior positions of the occiput. — Dr. Munde, whose paper was the most elaborate, dismissing occipito-posterior positions as "merely abnormal rotations or arrest of rotation of the two regular vertex presentations."

In 1878 Prof. A. Pinard, of Paris, published a most admirable monograph on Abdominal Palpation, which has recently (1885) been translated into English by Dr. L. Ernest Neale, of Baltimore, in which he treats in detail of the differential diagnosis of the posterior and anterior positions. This is, so far as I know, the first published account of how such a differential diagnosis can be made out. Some points that will aid the practitioner in arriving at a correct diagnosis are, however, not touched upon in Professor Pinard's article, and it is to these as well as to those to which he has called attention that I shall briefly allude in this paper.

Notwithstanding all these articles on the subject, judging from my own experience in consultation, with physicians, this method of making out the position of the fetus in utero is rarely practised except by the younger members of our profession fresh from the medical school or the continental clinics. Those who do practise it will, however, agree with me that, by the use of abdominal palpation, we are enabled, in the great majority of cases, to accurately make out not only the presentation but the position; a diagnosis

which should always be subsequently confirmed by a vaginal examination. In many cases where the labor has been tedious and the progress slow, the diagnosis per vaginam is difficult, unless it be preceded by an external examination, by which we can often easily make out the probable condition. This once known, a subsequent verification of the position by a vaginal examination is a matter of comparative ease. First, therefore, let us consider the method of making the diagnosis.

The woman should lie on her back with the legs extended and slightly separated. The examiner should stand on the level of the umbilicus, and on either side as is most convenient. Having assured himself that the bladder is empty, he should place his hands flat on the abdominal wall, telling the patient at the same time to make several deep expirations. In this way he is soon able to thoroughly examine the uterus and the pelvic cavity with their contents. On one side of the longitudinal axis of the uterus the resistance offered by the back of the child will be felt, while on the other side the resistance is much less marked and of a different character, being only that offered by the liquor amnii and the fetal extremities. The location of the dorsum is thus easily made out, and the occiput must be on the same side. Is it anterior or posterior? If it is posterior a more limited resisting surface is felt, and one which is more marked the farther one goes from the median line and the nearer the palpating hand reaches the lateral border of the uterus. If it is anterior the resisting surface passes to a greater or less degree over the median line, and, in many patients, the fetal vertebral column can be distinctly made out, which of course can never be done if the position is posterior. Moreover, as Pinard has noticed, the frontal end of the child's head being higher up in the mother's abdomen than the occiput,

is first reached by the hands of the examiner, and as the fingers approach nearer and nearer to the symphysis pubis the one which is on the side towards which the face points is first arrested, the flexion of the head allowing the hand over the occiput to pass lower into the pelvic cavity.

There are of course cases in which, owing to an unusual thickness of the abdominal wall or a large amount of liquor amnii, it is not possible to so accu-

ately map out the fetal outline in the manner described as to say positively whether the occiput is

anterior or posterior. But even in these cases an external examination will rarely fail to greatly facilitate the determination of the position. Those cases must be very exceptional in which we cannot, with absolute certainty, say on which side of the longitudinal uterine axis the back of the child lies. Given the situation of the back in the uterus, we know that the occiput, as has been already said, must be on the same side of the pelvis.

From a careful examination made early in labor of nearly 1,000 cases (981), occurring in my own practice and at the Boston Lying-In Hospital, I find that the head entered the superior pulvis strait in the right oblique diameter in 963, or 98 per cent. Nagelé, whose work on the subject has become classical, states this occurs in 99 per cent of all cases. I am aware that Dr. R. L. West takes exception to Nagelé's statement,<sup>1</sup> and claims that the head so entered the pelvis in only 60 per cent of a large number of cases in which he had an opportunity of making an early examination. The limits of this paper preclude any attempt to discuss West's elaborate paper on the subject, which, I think, however, open to several serious criticisms. My experience is in accord with the views of Nagelé, whose statement has also been accepted by nearly all the recent writers on the subject. If, therefore, an external examination shows us that the back of the child is in the mother's left, we know that the position must be that usually known as the first or occipito left anterior; for all observers, including even West, agree that the fourth or occipito left posterior is so rare as to be considered only as a very exceptional possibility. If, on the other hand, the child's back is found in the right, we may be dealing with either the second or third position, that is, with an occipito right posterior or anterior. A vaginal examination will, however, in many cases at once determine the position. If per vaginam the examining finger finds that the head is only just engaged at the superior strait, it is in all probability a posterior position; for it is in that diameter that the head usually enters the pelvis. If, on the other hand, the head has begun its descent, it may be either. It will enter in the right oblique; as it descends it may or may not have rotated, and an

<sup>1</sup> Glasgow Medical Journal, October, 1886, and January, 1887.

examination of the sutures and fontanelles will alone determine whether rotation has begun or not. In every case an examination per vaginam of the sutures and fontanelles should of course be made, for the purpose of confirming the diagnosis thus already made out. Practitioners who have never accustomed themselves to practise external examination will be astonished to find how, in the great majority of perplexing cases, the vaginal confirmatory examination will be found to be greatly facilitated by the knowledge previously acquired by manipulation of the abdomen.

So much then for the diagnosis of the posterior positions, and on their early recognition will the successful management of many of them depend. Some, in fact the great majority, take care of themselves; but every now and then the practitioner meets a case such as I attempted to describe in the beginning of this paper—a case in which his neglect to early recognize the position, allowed the patient to go from bad to worse, and resulted in an unscientific interference terminating in a way which is a disgrace to our knowledge of the true mechanism of labor.

One unvarying principle in this mechanism is, that the part of the fetus which is the lowest in its descent through the pelvis, must rotate forward under the arch of the pubes whenever it reaches the resistance offered by the lower pelvic strait. If the occiput presents in the posterior position as the labor progresses, and the head descends, the occiput must, therefore, when it reaches this resistance, rotate forward and become an anterior position. If, as the head descends, no such rotation takes place, it can only be because some other part of the head than the occiput has first reached the point where resistance is encountered, and that part, therefore, instead of the occiput, is then forced forward. This of course can only happen when there is lack of complete flexion, and, as a consequence, some other part of the fetal head than the occiput is lower and first meets resistance. In other words, whenever we find that a head presenting with the occiput posterior fails of an occipital forward rotation, we know that we are dealing with a head more or less extended. As the head in such cases descends, the expulsive force must act by driving the sinciput, which is the lowest part forward, and the occiput necessarily turns backwards into the hollow of the sacrum into which it is crowded, thus more and more shifting the pressure on the long arm of the lever and increasing the extension, the occipito-frontal diameter of the head taking the place of the sub-occipito-bregmatic. This gradual extension is readily detected by the greater ease with which the examining finger reaches the anterior fontanelle the lower the head descends.

The treatment of cases of occipito-posterior positions should be in the main what one might call prophylactic. The great majority of them require no treatment beyond a careful watching on the part of the attending physician. Governed by the principle that the lowest part of the presenting head must rotate forward, the occiput, though originally posterior, when it reaches the floor of the pelvis is rotated forward and assumes an anterior position. Rotation of the frontal end forward does, however, occur, as has been said, whenever there is a failure of proper flexion. West reports 79 such cases out of 2,585, a little over 3 per cent. It is to be regretted that in his admirable paper on the subject he does not tell us in how many of the whole number of cases the occiput presented poste-

riorly, in order that we might know in what percentage of such cases a failure of forward rotation of the occiput occurred. When such failure of forward occipital rotation occurs, the case at once becomes one involving more or less difficulty according as the head becomes more and more extended; the difficulty being of course only slight when there is only slight extension, and being most marked when extension is so great that the original vertex presentation has become converted into one of the face. The successful treatment of these cases must depend largely on the time when the diagnosis of the failure of proper flexion has been discovered, and the manner in which the attendant attempts to remedy the difficulty.

The diagnosis of a posterior position of the occiput having been made, the progress of the case should be carefully watched, with a view of an immediate detection of any failure of proper flexion. The posterior fontanelle should always be easily reached, while the lower the head descends the greater the difficulty in touching the anterior fontanelle, on account of the crowding of the frontal end of the fetus against the symphysis pubis. If at any time during the progress of the case the posterior fontanelle remains stationary while the anterior is becoming more and more easy of access, the attendant is at once conscious of a gradual extension of the head. It is at this time that an intelligent interference with the case can be of the greatest service. The fingers of the right hand, if the occiput be to the mother's right, should be applied to the frontal end of the head, and, during a pain, a firm resistance, not pressure, should be kept up to prevent any further descent, and the actual flexion of the head should be left to the pressure exercised on the occipital end by the force from above occasioned by the uterine contractions.

It not infrequently happens that the physician does not see the case, or, seeing the case does not recognize the threatening trouble, until the labor has so far advanced and the head has become so extended that the simple application of pressure, as advised in an earlier stage of the case, is no longer practicable. Occasionally such pressure, in conjunction with the vectis applied over the occiput, will, according to some writers, even at this late period of the labor, be found to be successful, although I have never been able myself to use the vectis under such circumstances with any very marked success. In such cases, or where the vectis has been tried and failed, I have several times been able to rectify the malposition of the head by a different application of the forceps from that in which they are generally used. It is to this method of delivery by forceps that I would especially call the attention of the members of the Society.

Where in posterior positions of the occiput the head has become to any degree extended, the use of the forceps, as usually applied, only serves, when traction is made, to increase the extension, thus facilitating the change of an occipital into a face presentation. The object I have endeavored to obtain in the use of the forceps in this class of cases, is not only to the descent of the head, but its flexion. Several times at the Boston Lying-In Hospital and in my own private and consultation practice, I have been able to overcome the existing difficulty, and to effect both the descent and flexion and consequent rotation of the head, by the application of the forceps reversed, that is, with the convexity of the pelvic curve toward the pubes instead

of toward the hollow of the sacrum as is usual. To effect this change of flexion, the blades should be introduced in such a way that the cephalic curve should pass over the ears of the child, the tips resting on the occiput. When traction is exerted, the forceps being so applied, the result must be that the main force of the traction is expended on the occiput, and, as the result, the occiput is drawn down and the head tilting on its attachment to the spinal column yields to the leverage thus applied, and the frontal end being forced

up the flexion of the head is at once established, and the occiput becomes the lowest part; the case can then be left to nature, and the forward rotation of the occiput soon takes place. The flexion is often facilitated by pressing the frontal end of the head upwards with one hand, while the occiput, held firmly within the blades of the forceps reversed, is drawn downwards with the other. If, owing to some emergency, immediate delivery is demanded, the forceps should always be taken off after the head has been flexed and then reapplied in the usual way, and the delivery effected; the operator favoring during the traction the forward rotation of the occiput. The extraction of the head with the forceps reversed is not a safe procedure, the tips of the blades tending to produce lacerations in the floor of the vagina and of the perineum.

In three cases, where all efforts at restoring the normal flexion of the head had failed, and the descent of the head had become arrested, owing to a want of adaptability between the fetal and pelvic diameters, I have seen further delay avoided and a successful and comparatively speedy result obtained to both mother and child by completely extending the head, thus converting a brow presentation at once into the most favorable variety of face presentation, namely, that in which the chin presents under the pubic arch.

The object sought in the preparation of the paper has been to insist upon the necessity of early making out the position, as well as the presentation, in every case of labor; the great advantage to be gained from the practice of an external palpation of the abdomen; in cases of posterior positions of the occiput the importance of an early recognition of any lack of flexion which will be liable to prevent the subsequent forward occipital rotation; the danger, if forceps are applied

to an extended head so situated, of still further increasing the extension, and the ease with which traction, applied on the occiput by means of the forceps reversed, not only restores the lack of flexion, but also facilitates the forward rotation of the occiput and the speedy and successful termination of the labor.

## THE PROPHYLACTIC TREATMENT OF OPHTHALMIA NEONATORUM.<sup>1</sup>

BY WALTER P. MANTON, M.D. (HARV.), OF DETROIT, MICH.

NEARLY two years ago I published a paper on this subject in the *American Journal of Obstetrics*,<sup>2</sup> but, as a large number of articles on the treatment of this disease have appeared, both in this country and abroad since then, it is my intention to-night, in a measure, to bring together these more recent observations and opinions of the treatment first inaugurated by Credé, of Leipsic, for the prevention of ophthalmia-blennorrhoea. It may, however, at the start be advisable to briefly consider this disease; its aetiology, and the treatment employed for its cure.

As regards the fatality of this ophthalmia to the eyes of the new-born, Lawrence says it "causes more blindness than any other inflammatory disorder that happens to the eyes."<sup>3</sup> Vogel<sup>4</sup> states that 80 to 90 per cent of all cases met with in practice affects the eyes of the new-born. Statistics go to show that in Germany and Austria the blindness found in the various asylums due to this disease is from 33<sup>5</sup> to 75<sup>6</sup> per cent; but I am unable to find any figures in regard to this in the United States.

In a country like ours, where the women of all classes are confined in their own houses, and lying-in hospitals are poorly patronized, the making of statistics on this point would be exceedingly difficult. Every practitioner, however, has met with such cases, and there can be no doubt but that, although the percentage is very much below that given by Vogel, the disease is sufficiently common to make it an object of dread.

If the importance of sore eyes in the baby could be impressed upon mothers and nurses, and cases could be treated from the beginning, the results would not be as disastrous; for, as Williams<sup>7</sup> says, "no disease is more fatal to the eyes when neglected or improperly managed"; while, on the other hand, "none offered better results from judicious treatment, for even in its worst form it is always curable."<sup>8</sup>

Not every inflammation of the eyes met with is a purulent ophthalmia, and yet in the early stages it is often impossible to determine whether the conditions present are harmless or vicious. For this reason the accoucheur should warn the attendant to notify him at the first indication of trouble with the infant's eyes.

Ophthalmia neonatorum usually begins several days after birth. It may appear as late as the ninth day, but this late development is so rare that of fifty-one cases affected with the disease, out of 1,692 chil-

dren, the period of incubation was nine days in only two instances. In the very large majority of cases the blennorrhœa appeared before the fifth day; so that we are safe in assuming that all cases developed after that period are due to infection after birth from dirty hands, lochia, etc.

The disease usually begins in a way which is far from alarming the attendant of the child — and much mischief may be done before it is brought to the physician for treatment. Thus a case is mentioned by Ryall,<sup>1</sup> of Dublin, in which the mother brought both lenses of her baby's eyes, and some of the vitreous humor, in a wineglass, when applying for assistance.

The first symptom to be noticed in ophthalmoblennorrhœa, is a slight reddening of the skin of the upper eyelid, accompanied by a watery discharge from the eye, and photophobia. If the conjunctiva is inspected it will be found reddened and velvety. By the next day, or even in a few hours, the lids, and particularly the upper, will be found enormously swollen and livid, and the secretion, becoming more and more purulent, is poured out in quantity. "The upper lid," says Nettleship,<sup>2</sup> "hangs down over the lower and is often so stiff that it cannot be completely everted."

The lids often become glued together by the dried pus along their edges, and the pent up and increasing secretion behind causes them to bulge forward. If, at this stage, the lids be carefully drawn apart — and the greatest care is necessary lest the cornea, perhaps already damaged, be ruptured — the conjunctiva, bathed in pus, will be found greatly injected, and hemorrhage will occur even with the most tender handling. The great danger from this disease lies in the strangulation of the blood-vessels, and the local influence of the purulent discharge. These, if left to themselves, are very apt to lead to extensive corneal sloughing, or the formation of deep ulcers and perforation.

The aetiology of this disease is now pretty well established. It is caused by a specific virus which is identical with that of gonorrhœa. This virus, like all other important matters now-a-days investigated, has a micrococcus of its own, or rather one which it shares with the discharge of gonorrhœa. This coccus was discovered by Prof. Alb. Neisser in gonorrhœal pus, and named by him gonococcus. The cocci form colonies of ten or twenty individuals, and are enclosed in a sheath of mucus; but as a peculiarity they are never seen in close contact with one another. Usually they are seen adhering to pus corpuscles, but occasionally are found on epithelial cells. They possess an affinity for methylviolet and dalia, and may also be colored, but not so distinctly by eosin. The method employed for their detection is that of Koch.

In all the gonorrhœal pus examined by Neisser, the characteristic coccus appeared, but in no other, save in ophthalmoblennorrhœal pus was it to be found. The constancy of this coccus in gonorrhœal discharge has been further proved by the researches of Weiss, Ehrlich, Sattler, and others. Sattler, and others have also attempted the "pure" culture of this micrococcus, but as yet have not met with complete success in their experiments.

Shurmer<sup>3</sup> reports a case of a six-day old child, in perfect health, with a healthy mother, whose eyes

became infected by lochial secretions. In forty hours an ophthalmia was produced and in the secretions from the eyes Sattler found the gonococcus.

Zweifel,<sup>4</sup> of Erlangen, experimented with six healthy children, having healthy mothers, the absence of syphilis, gonorrhœa, etc., in whom during pregnancy was positively ascertained. Lochial discharge from these mothers were placed in the children's eyes, the result being an inflammation in one case. This, Zweifel thought to be a genuine ophthalmoblennorrhœa, but it was discovered that the father of the child lay sick with diphtheria in the same room, and the secretions from the child's eyes, which were examined by Sattler, were found to be *diphtheretic only*.

Without going further into the discussion of this point, it is very evident that ophthalmia neonatorum is caused by a specific, active principle, not yet isolated, found in the secretions of gonorrhœa.

The predisposing causes of this blennorrhœa, according to the investigations of Credé,<sup>5</sup> are a premature rupture of the membranes, and a prolonged second stage; that is, anything over one hour.

All treatment of ophthalmia neonatorum heretofore has been directed to the disease after its presence has become evident. This has consisted in such household remedies as breast milk, pieces of human placenta, salves, etc., or the more radical professional treatment with caustics and the like. Since Credé's first article appeared, various methods or modifications of the treatment advocated have been tried. These have generally consisted in washing out the vagina with antiseptics before and during labor; immediately wiping the child's eyes as soon as the head is born, with cotton or bits of rags wet in carbolic, salicylic, or boric acid lotion; irrigation of child's eyes with carbolic lotion or plain water, etc., and have been more or less successful.

Credé's<sup>6</sup> own first attempts were directed to the mother. Each pregnant woman entering his hospital with gonorrhœa or leucorrhœa had the vagina washed out with an antiseptic lotion at frequent intervals; and the lying-in underwent this treatment every half hour. This diminished somewhat the frequency of ophthalmoblennorrhœa, but was not altogether satisfactory.

Attention was then turned to the eyes of the child, which received a drop of a weak solution of borax (1:60). This also proving unsuccessful, Credé left off washing out the vagina, December, 1879, and began cleansing the eyes of the child with a solution of salicylic acid (2:1000), a single drop of a solution of nitrate of silver (1:10) was then allowed to fall between the lids, and the eyes were kept cool for twenty-four hours by bits of cotton wet in the salicylic lotion. Finally a two-per-cent solution (1:50) of nitrate of silver was used after the bath, and no further attention was paid to the child's eyes. This treatment practically reduced the percentage of ophthalmoblennorrhœa to 0 in Credé's clinic.

During the early part of 1884 Credé published a pamphlet<sup>7</sup> in which he not only reviews his own experience in this treatment, — extending over a period of about five years, — but has also collected the writings of all others on this subject up to date of publication. The general verdict being in nearly every instance favorable to the method.

<sup>1</sup> *Tr. Soc. of Ed. of College of Physicians in Ireland*, Vol. IV, p. 100.

<sup>2</sup> *Diseases of the Eye*, London, 1904, p. 76.

<sup>3</sup> *Vierteljahrsschrift der Naturforschenden Gesellschaft in Zürich*, p. 35, also Bd. XXIII, p. 275.

<sup>4</sup> *Centralblatt f. Gynäkologie*, 1882, p. 209.

<sup>5</sup> *Separatdruck aus d. Arch. f. Gynäk. u. Bd. xxi., Heft 2, 1882.*

<sup>6</sup> *Arch. f. Gynäkologie*, Bd. xxi., p. 50; also Bd. xviii., p. 307.

<sup>7</sup> *Die Verhütung der Augenentzündung der Neugeborenen*, Berlin, 1884.

Since the publication of my own paper on this subject, I have seen a large number of children treated by Credé's method in the clinics of Vienna and elsewhere, and I cannot recall a single case of the disease where the application has been carefully and thoroughly made.

Leopold<sup>1</sup> reports from the Dresden Lying-in Hospital a series of 1000 cases thus treated, with three cases, or 0.3 per cent of ophthalmia neonatorum. In 522 additional cases, where the application was made each time by an assistant, the nurses having nothing to do with it, the percentage of blennorrhœa was reduced to 0.

Beumer and Peiper<sup>2</sup> report from the Kliniek and Poli-Kliniek of Greifswald, where the percentage of ophthalmia neonatorum has, during a period of twenty-four years, varied between 1.7 per cent and 30.8 per cent that "with the adoption of Credé's prophylactic treatment with nitrate of silver, the change was at once evident. There were, indeed, a few cases of the disease, but these were of such a light degree that they can hardly be called blennorrhœa, especially as they for the most part yielded at once to the treatment with sulphate of zinc, or Boracic acid, being cured in a few days."

The most recent report from our own country comes from Dr. Garrigues<sup>3</sup> of New York, who found that of 351 children treated by this method in the Maternity Hospital, not one was affected with ophthalmia-blennorrhœa. The perfect results now obtained by Credé's method, make it obligatory in every lying-in institution to adopt this treatment. And, as the disease is also met with more or less frequently in private practice, no physician should consider his obstetrical armamentarium complete without a small bottle of a two-per-cent nitrate of silver solution. And in every case where there is a history of specific disease, or leucorrhœa or other discharge from the genitals during pregnancy, it should be the care of the accoucheur to see that the child's eyes are properly treated prophylactically. The *modus operandi* is so simple that it requires no experience or training in its carrying out. After the bath the child's eyes should be wiped with a bit of cotton or linen rag wet in clean water, every particle of smegma, etc., being thoroughly removed. The lids should then be carefully separated by the thumb and fore finger of the left hand, while with the right a single drop of the silver solution is allowed to fall from a glass rod into the middle of the cornea. With a clean bit of rag wet in water, the eyes are again wiped and dried. Further treatment there is none. It is well to see that the tip of the glass rod is smooth and rounded so that if coming in contact with the cornea, it can produce no injury.

#### COMBINED VERSION (BY INTERNAL AND EXTERNAL MANIPULATION) IN PLACENTA PRÆVIA, WITH REPORT OF A CASE.

BY J. S. HALL, M. D. (HARV.), STERLING, COLORADO.

The case following is reported as showing the value of the method of version by combined internal and external manipulation in placenta prævia in cases of emergency, where a consultation is impossible and all that is done must be done by the physician with the aid only of such assistants as may be found in any house.

Mrs. J. P. G., married, twenty-four years old, fourth pregnancy. Last menstruation June 12th to 15th. On January 5th, hemorrhage occurred, estimated at a pint and recurring on 12th, advice was sought. Although there was complete placenta prævia, temporizing measures were adopted until June 26th, two or three slight floodings occurring meanwhile. After a hemorrhage of half a pint on that day, induction of labor was decided upon, the os being soft and admitting the finger easily. The nearest available medical assistance being one hundred miles distant, the operation was done with the assistance of the husband and two women of the house. Complete anesthesia by ether being regarded as of doubtful expediency under these circumstances, the woman was allowed to inhale chloroform to the extent of becoming only partially unconscious. At 9:20 A. M., the forefinger was introduced into the os, and in about thirty minutes the placenta was detached upon the right, a foot seized, and, by assistance of the left hand externally, was brought down, two fingers only having been passed into the uterus. Traction on the foot checked all hemorrhage, and, in ninety-five minutes from the beginning of the operation, a male child weighing five pounds was delivered. The fetal heart had been heard in right flank, 120 per minute, and a boy predicted.

Placenta immediately expelled by Credé's method, and total loss of blood in the labor estimated at a pint.

The after-treatment was the same as in ordinary labors, and mother and child did uninterruptedly well.

#### REPORT ON THE PROGRESS OF LARYNGOLOGY AND RHINOLOGY.

BY FRANKLIN H. ROOPER, M.D., BOSTON.

PHOTOGRAPHY OF THE LARYNX.

Among the progressive steps that have recently been taken in matters pertaining to this report, we must mention the perfection to which the art of photographing the human larynx has been brought, owing to the perseverance and skill of Dr. Thomas R. French, of Brooklyn, N. Y.

Dr. French read a paper on this subject at Copenhagen (International Medical Congress, August, 1884), and again, by invitation, last April before the College of Physicians, Philadelphia. We are indebted to the courtesy of the Committee on Publication of that society for the cuts accompanying this report.

In his paper the author states that he believes that photography of the larynx will prove of value. 1. By enabling us to obtain exact reproductions of the laryngeal image, thereby furnishing truthful illustrations for published reports of cases. 2. In the study of the physiology and the pathology of the larynx. 3. By enabling us to show photographs with the lantern for class-room instruction. The manner in which the larynx is photographed may be seen from this sketch (Fig. 1).

In the window is an instrument by means of which the sun's rays are concentrated. It consists of a hollow truncated cone of metal, ten inches long, in the large end of which is a double convex lens. In the small end is a plano-convex lens which intercepts the converging rays of the large lens and makes them parallel. The beam of light is caught upon the head-reflector, and reflected into the nares of the subject.

In the examiner's right hand is seen the camera. Within the camera is a drop-shutter. This is governed

<sup>1</sup> Arch. Gynecologie. (B.) xciv, p. 91, 1881.

<sup>2</sup> Arch. Gynecologie. (B.) xciv, p. 179, 1881.

<sup>3</sup> American Journal of Medical Science, October, 1881.

by a spring which is under the control of the fore-finger. A holder, containing a plate, is inserted through a door on the back of the camera. The plate is so arranged that, by sliding it up and down, five photographs can be taken upon it.

Now, when the examiner sees with his left eye, through the opening in the reflector, the image of the various structures of the larynx, in the throat mirror,

Fig. 1.

in the position in which he wishes to photograph them, he presses upon the spring with his index finger, the shutter falls, and the exposure is made. In this way five photographs can be taken in from three to five minutes.

There is an effect shown in the photographs which cannot be so well shown in drawing; that is *depth*.

This photograph (Fig. 2) was taken of the larynx of a lady while singing a tone in the soprano voice.

Fig. 2.

The vocal bands are seen to be short. They are not as short as they appear to be, for the epiglottis over-

Fig. 3.

hangs the larynx somewhat, and cuts off a view of a part of them, but they are really quite short. Short

vocal bands in the female indicate, as a rule, that the subject has a soprano voice.

This (Fig. 3) was taken of the larynx of a professional contralto singer, while singing the note E, treble clef, fourth space. The vocal bands are long, and long vocal bands in the female indicate, as a rule, that the subject has a contralto voice. The chink of the glottis is seen to be open widest in its posterior part. Dr. French believes that the position of the vocal bands, in different larynges, in the production of the same tone, in the same class of voice, almost always differs.

This photograph (Fig. 4) was taken of the larynx of a gentleman while singing a tone in the tenor voice.

Fig. 4.

Unfortunately, at the time that the photograph was taken, he was suffering from an attack of acute laryngitis, which accounts for the presence of mucus in the chink of the glottis, as well as upon one arytenoid cartilage. The vocal bands are seen to be short, and when we find short vocal bands in the male, we can feel quite certain that the subject has a tenor voice.

Fig. 5.

This (Fig. 5) is a photograph of the larynx of a bass singer while singing the note B, bass clef. The vocal bands are seen to be long. They are usually long in subjects having bass voices. In this picture we see that the vocal bands are in contact at their posterior insertions, leaving an opening in front, which is widest just in front of the point in contact, and a very small opening behind. The position of the vocal bands as seen in this larynx does not agree with any description which Dr. French has seen, of the mechanism in the production of low tones in the bass voice. In larynges

Fig. 6.

of other subjects having bass voices, while singing in the same tone, the chink may have an elliptical shape, and be open in its entire length.

The preceding drawing (Fig. 6), is of the larynx of a young lady, sixteen years of age, who possessed the extraordinary compass of four octaves, and could sing as high as C' above the high C'. Dr. Cohen, in his ex-

cellent little book, "The Throat and the Voice," tells us that La Bastardella could sing this note, and that, for its production the vocal bands must vibrate 2100 times in a second. Dr. French was fortunate enough to secure a photograph while she was singing her highest note. You will observe that the vocal bands are very narrow, quite long, and in very close apposition. Of course, they were being subjected to the highest degree of tension. He was also successful in getting a photograph of her larynx while she was singing her lowest note, C, bass clef, second space (Fig. 7). Here you see that the vocal bands are very short, very broad, and not in close apposition. They become

Fig. 7.

longer and narrower, and are brought into closer apposition as the voice ascends the scale.

(Excellent as these drawings are, they convey but an imperfect idea of the beauty of the original photographs.—*Rep.*)

#### LARYNGEAL PARALYSIS AND INEQUALITY OF THE PUPILS, AS TENDING TO AID AND ALSO TO MISLEAD IN THE DIAGNOSIS OF THORACIC ANEURYSM.

Dr. James Finlayson, in the *Lancet*, January 3, 1885, reports two cases of patients who were in his wards at the same time which afforded illustrations of the value of these signs, and also of the danger of trusting too much to their significance. There was nothing remarkable about the first case apart from the fact that the aneurysm was of the arch of the aorta, and yet the right vocal band was the one paralyzed. The dyspnea was often extreme, and he had had several attacks, almost fatal in character, due to spasm of the glottis, terminating with a crowing inspiration. The right pupil was smaller than the left. Dr. Finlayson discusses at some length the state of the pupils after death and the effect of atropine.

In the second case, where the signs of laryngeal paralysis and inequality of the pupils were misleading, there were obvious signs and symptoms of cardiac disease. But there was also evidence of dilated aorta. Moreover, there was at times a very distinct sense of impulse immediately under the left clavicle. There was also substernal pain, and this extended down the left arm, but there was no swelling. The pulses were throughout quite equal, and the tracings had a well-marked aortic regurgitant character. The left vocal band was paralyzed.

At the post-mortem examination the aneurysm so confidently looked for in the left side did not exist; there was, indeed, a dilated aorta, and even the beginning of a small pouching towards the right side just above the valves. The aortic valves were quite incompetent, much diseased, and very hard and calcareous; the heart was enormously enlarged. The cause of the left-sided laryngeal paralysis seemed to be due to the state of the left lung, which was found adherent and of a brownish color; it had the appearance of being compressed and shrunken. The recurrent laryngeal nerve was found to pass through a mass of enlarged glands, just at the arch of the aorta. The

explanation of the laryngeal paralysis seemed to depend on the dragging downwards of the left recurrent nerve, due to the greatly enlarged heart, and favored by the shrunken left lung. The implication of the recurrent nerve in the glands cannot be wholly set aside, although their softness would no doubt lessen the chance of their causing irritation, or, at least, of producing paralysis. We must, therefore, the writer concludes, bear in mind that the occurrence of laryngeal paralysis on one side, in the course of a case with symptoms pointing to the chest and strongly suggestive of aneurism, does not necessarily imply the existence of aneurysmal disease or of thoracic tumor.

#### RESPIRATORY CROAKING OF BABIES.

Dr. Samuel Gee has seen about a dozen cases of what he calls respiratory croaking in babies, and thus describes the affection in Saint Bartholomew's Hospital Reports, Vol. xx, 1884. Breathing is accompanied by a croaking noise, which seemed to Dr. Gee to have the characters of stertor more than of stridor; or, in other words, the sound seemed to be produced in the fauces and not in the larynx. The croaking usually accompanies inspiration only, but in one of the cases it accompanied expiration only. The noise is constant, both when the child is awake and when she is asleep; yet it may cease for a short time now and then. The tone of the cry is natural, and this is another reason for believing the noise not to be laryngeal. No dyspnea, no recession of chest wall during inspiration. Faeuces look natural. The noise continues when the nose is pinched. The croaking has nothing whatever to do with the crowing of laryngismus stridulus; the two disorders resemble each other in no respect, except that there is a noise produced in each. The ages of Dr. Gee's patients ranged from three to nine months. It is a remarkable fact that all of them were girls. The general health of some of the children was good, but most of them were weak and sickly. Two children suffered from congenital diseases of the heart, and one was an idiot. In some of the children this croaking began at or soon after birth, and in no case did it last much beyond the end of the first year. There is no special treatment; indeed, the disorder causes more annoyance to others than to the child herself.

Joseph Frank, in his "Praxis Medica" (De Morbis Laryngis, Cap. ii., Sect. 11), refers to observations of Storch which somewhat resemble these. But most of Storch's patients were older than Dr. Gee's, and he seems to have confused all kinds of stertor and stridor together. There is a much better description of the disorder in Rilliet and Barthez' book, "Des Maladies des Enfants," under the name of "Trachée de la Première Enfance," but Dr. Gee's description, he says in conclusion, is wholly upon facts within his own experience.

#### DEFECTIVE WIND IN HORSES.

William Hunting, F.R.C.V.S., in a popular article on this subject in *Baily's Magazine*, December, 1881, points out that the abnormal sound made by a horse in his breathing when galloped, which is called "roaring," is due in ninety per cent of cases to a paralysis of one of the posterior cricoarytenoid muscles. This condition, as in man, adults, in the vast majority of cases, of no cure and is certain to become progressively worse. It is remarkable that in the horse, according to Mr. Hunting, that it is always the left

muscle which fails to act, and after death this muscle is found to be greatly atrophied. In some cases both muscles are more or less affected, and then but very little excitement is necessary to bring about suffocation. Horses with bilateral paralysis of the abductors are rendered serviceable by the performance of tracheotomy, and in the cases in London they are often seen doing useful work while wearing their tubes. (The etiology and pathology of paralysis of the abductor muscles of the larynx—whether bilateral or unilateral—is one of the important questions of the day to laryngologists, and it is not unlikely that we may get some useful hints from analogous conditions in our dumb friends. We question, however, whether this condition in the horse be not due to complete paralysis of the recurrent nerve and not to any one particular muscle.—*Rep.*)

#### CASEOUS GLANDS IN THE TRACHEA CAUSING SUD- DEN DEATH.

Two cases of this rare affection have been reported within the past year. One by Dr. Percy Kidd,<sup>1</sup> of London, and the other by Dr. Janeway, at the New York County Medical Association meeting, March 16, 1885. A third case which came under the care of Professor Petersen-Kiel<sup>2</sup> is interesting as showing the result of treatment. Dr. Kidd's specimen was taken from the body of a boy, aged seven. He was noticed to have a croupy cough and somewhat stridulous breathing during life. One night, after running about in the daytime and having complained of no urgent symptoms, he suddenly awoke, screaming, coughing, and struggling for breath. He died in about ten minutes. At the autopsy the mediastinal glands were all enlarged and caseous; the enlargement was most marked of those glands lying in front of the trachea; the lower end of the trachea was blocked by an oval, partially softened caseous gland, which had been extruded through an ulcerated opening in the anterior wall of the trachea, just above the orifice of the left bronchus. The perforation led into an encapsulated space in front of the trachea, which contained caseous debris and traces of gland tissue. The lungs contained a few milary tubercles in their upper lobes, but were otherwise healthy. The heart was firmly contracted and practically empty, and was quite healthy. All the other viscera were healthy. It was remarkable that although the child evidently died of asphyxia, there was no distension of the right side of the heart found after death.

Dr. Janeway's specimen also came from a child who had died very suddenly from asphyxia. At the autopsy a cheesy gland was found at the bifurcation of the trachea, which had produced ulceration, while occluding the stenosed passage was a white mass which had undoubtedly become detached from this, but which was at first mistaken for coagulated milk. In addition, there was a fibroid induration of the upper lobe of the right lung, and a thickening around the bronchi. Two physicians had expressed the opinion that this child had died of paralysis of the heart; but paralysis of the heart, like the term malaria, was often used merely as a convenient expression to conceal ignorance. What was believed to be paralysis could only be determined by an autopsy. Dr. Janeway said, in

conclusion, that when stridor was heard in connection with tracheal breathing, it should always attract attention to the glands of the part.

Professor Petersen-Kiel's patient was a child aged six years, with a history of hereditary tuberculosis, but externally showed no indication of scrofulosis, and had recovered from a severe attack of German measles complicated with bronchitis. She was subject to frequent attacks of asthma, which progressively became more severe. At last she was brought to the hospital, and the dyspnea was so severe that death was imminent, and tracheotomy was hurriedly decided upon and performed. As a result of the operation, the breathing became but little easier, and it was evident, therefore, that the obstruction was below the incision. In order to determine the exact condition, Professor Petersen-Kiel then introduced an elastic bougie into the trachea, which met with no obstruction until it reached the bifurcation. Upon withdrawing the bougie, crumbling masses of caseous matter were found adherent to it, whereby it was rendered clear that the impediment was due to a caseous gland. By means of a Nélaton catheter, the end of which was cut off, a collection of cheesy matter, more or less calcified, was removed.

The breathing now became freer. No canula was introduced into the trachea, but the edges of the wound kept open by silk stitches. The child soon fell asleep. During the night following the operation, more caseous matter was evacuated in efforts of coughing. The patient recovered without accident, and the wound, made by operation, healed in twenty-three days. No abnormal condition existed in the lungs, and the portions of the glands evacuated contained no tubercle bacilli.

#### ACUTE MENINGITIS IN RELATION TO DISEASE OF THE NASAL MUCOUS MEMBRANE.

Interest in this subject, to which attention was long ago called by Mr. W. Spencer Watson and others, has recently been revived in England. Mr. Watson states that the important point in the clinical aspect of these cases is that the intra-cranial symptoms came on very insidiously, and that the nasal disease is often quite overlooked, so that the appearance of meningitis seems inexplicable, or is attributed to some other cause. Mr. Frank Ogston,<sup>3</sup> reports a case in which the post-mortem examination showed that the exciting cause was an inflammation of the nasal mucous membrane which had spread through the orbital plate of the ethmoid bone and the dura mater to the arachnoid membrane which it had attacked, and the inflammation had spread along the subarachnoid space. Dr. Ogston's report of the appearance, which directly concerns us here, says that a careful examination of the dura mater showed that it was healthy, except a small patch which covered the orbit, which was thickened, roughened on the side next the bone, and covered with a layer of lymph on the side next the brain, by which it was glued to the arachnoid. The orbital plate of the right side presented a canary-yellow appearance, and a congested and roughened state of the bone. On cutting this through, the nasal cavity was found to be filled with thick creamy pus, which welled out into the brain cavity.

This interesting case of Dr. Ogston's called forth, in the succeeding number of the same journal, a communication from Dr. McNaught, of Newchurch, who

<sup>1</sup> London Medical Times and Gazette, February 21, 1885.

<sup>2</sup> Deut. Med. Wochenschr., March 5th. Phila. Med. News, April 10th, 1885.

<sup>3</sup> British Medical Journal, May 16, 1885.

reports two nearly similar cases, both attended by fatal results, but no post-mortem examinations could be obtained. In both of these cases a very profuse discharge of fetid pus took place suddenly from both nostrils. Although there was nothing specially pointing to the frontal sinuses in these cases, Dr. McNaught thinks that there can be little doubt that the meningitis had been set up by continuity from inflammation of the mucous membrane lining these cavities. He suggests that if early inquiries be directed to the condition of the frontal sinuses, and careful attention paid to the symptoms, we may be enabled to distinguish these cases, and by early trephining, or otherwise giving exit to the pus, a favorable result may be obtained.

#### TREPHINING THE FRONTAL SINUSES.<sup>1</sup>

In a recent number of the *Medical Chronicle*, Mr. OGSTON, of Aberdeen, states that he has practised the operation in several cases of obstinate catarrhal disease in which other treatment was unavailable. The symptoms indicating this measure were constant pain at the root of the nose and above the orbits, increased on deep pressure, with periodical discharges of thick, yellow pus. The operation consists in making a vertical incision two centimetres long in a median line, between the eyebrows, after which the periosteum is carefully lifted from the bone and the sinuses are opened with a small trephine. The diseased mucous membrane is removed with a sharp spoon, and a strong solution of chloride of zinc is applied to the interior of the cavity. Drainage is established through the nose.

This radical procedure (by no means new, since it was practiced by von Langenbeck) has received a decided impetus at Mr. Ogston's hands; but, in spite of the fact that he reports a cure in every case, and with no recurrence of the trouble, conservative surgeons will be apt to hesitate before resorting to a measure that seems to be of such an heroic nature.

#### TREATMENT OF DEFORMITIES OF THE NOSE FOLLOWING INJURY.<sup>2</sup>

W. J. WALSHAM, F.R.C.S., Surgeon in charge of the orthopaedic department at St. Bartholomew's Hospital, treats old injuries of the nose which have resulted in fractures or displacement of the nasal bones or cartilages, by means of a mask accurately moulded to the face to keep the parts in place until they have had time to consolidate. His method is as follows: A plaster-of-Paris cast is first taken of the face, and in this the leather for the mask is moulded, apertures being left for the mouth, eyes, and nose itself. The mask, when thoroughly dry is lined with soft chamois leather, and fits accurately to the irregularities of the face, so that no movement can take place. It is secured by suitably arranged straps around the head. Having thus attained a fixed point to work from in the mask, it is easy to bring pressure to bear upon the nose in any direction required by suitable screws, springs, etc., attached to the mask. An illustration of the mask accompanies Dr. Walsham's remarks, which he claims he has used with good results.

#### THE CURE OF CROOKED NOSES BY A NEW METHOD.

At a meeting of the Philadelphia County Medical Society, Sept. 17th, 1884, Dr. JOHN B. ROBERTS presented a patient who was undergoing treatment for a lateral deformity of the nose which resulted from a fall ten years previously, the man recovering with the

end of the nose bent to the right, and with considerable obstruction of the left nostril. Dr. Roberts thus describes his original method of treatment: "With a scalpel introduced through the left nostril, I perforated the cartilaginous septum at its upper and back part, and made a long incision through it in a direction downwards and forwards. This permitted me to push the whole of the external portion of the nose to the left, thereby straightening the cartilaginous septum, and overcoming to a great extent the lateral deformity. To retain the parts in this position, I introduced a steel pin, about one and one-fourth inches long, into the right nostril, and passed it completely through the anterior and upper segment of the divided septum, near the columella. Having the unmovable portion of the septum thus transfixed, I was enabled, by carrying the head of the pin to the left, to move the anterior part of the nose to the left, and retain it there by imbedding the point of the pin deeply in the unmovable cartilaginous septum and mucous membrane at the back of the left naris. In other words, I incised the deformed cartilage, and pinned it in position very much as you would pin a flower in the button-hole of a coat." The novelty of Dr. Robert's method consists merely in pinning the parts in position until cicatrization takes place—a method, he claims, which leaves no noticeable scar, is not troublesome to the patient, and is applicable to those slight deformities whose chief annoyance is an æsthetic and cosmetic one. The pins are left in position about two weeks.

#### PERFORATING ULCERS OF THE SEPTUM NASI.<sup>3</sup>

JONATHAN HUTCHINSON, F.R.S., in a clinical lecture on the above subject, details twelve cases out of a large number that he has observed to illustrate and prove his statement that chronic perforating ulcers of the septum nasi occur not infrequently under conditions which preclude the suspicion of syphilis. He refers to a very slowly progressive ulcer, which is usually situated just within the nostril, or about half an inch from the edge of the columella. It always begins first on one side, and does not affect the other until a considerable interval has passed, and there is usually a period of several months, or perhaps years, of superficial opposite ulcers before the final perforation takes place. Sometimes they are of the nature of lupus, and the younger the patient the more likely it is that they have this relationship. They are most common after middle age, and in not a few patients at this period of life it is impossible to assert anything with confidence as regards their cause. Even when there is a clear history of syphilitic antecedents, if the ulceration be very slow and without tendency to diffuse inflammation or to exfoliation of bone, it will usually be found that internal treatment by specifics does very little good, whilst local treatment will cure. The best local treatment is the repeated careful application of the acid nitrate of mercury, and the use of yellow oxide ointment.

— It is said that there are at present at the various German universities no fewer than 157 professors between the ages of 70 and 90. Of these 122 deliver their lectures as usual. The oldest is the veteran Von Ranke, the historian who is now in his 90th year, but is not considered fully equal in vigor, memory and other faculties to Professor Eichenich, who is thirty-nine days his junior.

## Reports of Societies.

### NEW YORK COUNTY MEDICAL CONVENTION.

STATED meeting, June 15, 1885.

DR. FRANK H. HAMILTON presented a paper, which was read by Dr. John Shradly, the corresponding secretary, with the title:

#### A FEW PRACTICAL REMARKS ON RUPTURE OF THE PERINEUM.

Obstetricians, he said, had frequently given instructions how to avoid this accident, and had sometimes intimated that its occurrence always implied negligence on the part of the accoucheur. It was unjust, however, he thought, to say that it could always, or even generally, be prevented by the skill of the latter, since its occurrence was often due to conditions and circumstances over which the accoucheur had no control. Thus, the perineum might be unusually thin in the antero-posterior diameter, or unusually thin and delicate, or less elastic in its texture than natural; the sacrum and coccyx might not have the proper curve to direct the head toward the pubes; the head itself might be large and unyielding; the uterine contractions might be too violent and rapid to allow the perineum time to become gradually stretched and accommodated to the head.

He was convinced that the idea of "supporting the perineum" as it was called, could not be sustained by any mere mechanical theory or by experience, except when the purpose of making pressure upon the perineum was to carry the head forward toward the pubes in those rare cases in which, from the lack of curve in the sacrum and coccyx, or from any other cause, the vertex did not take this direction. It did not follow from anything that he had said that the accoucheur might not sometimes be responsible for rupture of the perineum, but his responsibility was likely to consist in what he might actually have done, rather than in what he might have omitted to do; the accident not infrequently being due to his improper haste. Some modern gynecologists did not think the danger of rupture increased by the use of the forceps, if only they were used skillfully; but it certainly would increase the danger if the instruments were used unskillfully, and also when, even in the hands of the most skillful, the forceps were retained in position until the head had entirely escaped from the vulva. Nor did it appear to him that the arguments in their defence was conclusive, even when they are only employed to bring the head into the lower strait, by which manoeuvre it was claimed that the process of natural labor might often be greatly expedited. This was the very thing which it was generally most desirable to avoid, so that, as Meigs used to say, the perineum might "not be taken by surprise." In short, there was less danger to the perineum when the head did not come upon it forcibly and unexpectedly, and before the head itself had undergone the process of moulding and elongation.

Dr. Hamilton spoke at length of the great change in regard to the much more frequent use of both anaesthetics and the forceps in obstetrical practice since he had started in professional life, and summed up by saying that, while there could be no question that the forceps and anaesthetics had been of incal-

able service to parturient women, he had a strong conviction that since they have come into common and almost universal use, they have done a great deal of harm. He therefore believed that the time would come, and at no distant period, when it would become apparent to all that we have in these matters progressed too rapidly, and finally, that our progress has been altogether in the wrong direction. He next referred briefly to the various degrees of rupture, and then went on to say that the concurrence of a deficient perineum and of prolapsus uteri did not always stand in the relation of cause and effect. The uterus might be made to descend from many causes whether the perineum is sound or not, and the absence of the perineum, when the vagina and uterus were in their normal conditions, could only influence the descent of the uterus by first inducing atony of the muscular fibres of the vagina, with congestion and prolapsus of the vaginal walls, by which not only the feeble and indirect support which the perineum gave to the uterus was removed, but the vaginal walls became actually a dead weight to drag the uterus downward.

He expressed himself as entirely opposed to the immediate or primary operation for ruptured perineum. Among the reasons which he gave for this position are the following: The parts had suffered such a degree of stretching and contusion as to render the occurrence of inflammatory reaction, if not of sloughing, almost inevitable; the lochial discharges would make it impossible to keep the parts clean; the operation itself inflicted a severe injury when the condition of the patient was already critical from other causes, and finally, because under most judicious management the rent frequently became partially and sufficiently closed spontaneously. From any point of view, he said, it came to this, that it was proposed to make an operation by no means trivial in its character, not to speak of the subsequent special management of the bowels required, and which operation at the best was very liable to fail; and which might subsequently in case no operation was performed, be found to have been unnecessary, or which, if it became necessary, could be done more thoroughly and successfully at a later period. It was proposed, therefore, to make the operation under every surgical disadvantage, and when the patient, prostrated and trembling from the results of a severe labor, was in the worst possible condition, both mentally and physically, to endure the shock of an operation, or even its announcement. Nothing but the most urgent necessity could justify the operation under these circumstances, and this necessity had not been shown to exist. At this early period, moreover, it was often difficult for an expert even to form anything like a definite opinion as to the actual extent of the lesion. A rent, which at first seemed to be an inch or two in length, on account of the distended condition of the perineum, would, after contraction, a few hours later be found to be not more than a quarter or half an inch.

The paper described in conclusion, the secondary operation, with its preparatory and after treatment. He employed the quilled suture (only using sections of a large-sized flexible bougie for the quill), in preference to the wire suture on account of the more difficult introduction and removal of the latter. If, however, the rent or loss of structure involved any considerable portion of the recto-vaginal septum he

said he would recommend, so far at least as the rectal fissure was concerned, the wire suture either with or without Bozeman's clamp.

At the conclusion of the reading of the paper, Dr. Hamilton made a few extemporaneous remarks in which he argued against the views of Dr. Fordyce Barker in regard to the effect of chloroform in labor, and went on to say that as to the frequency of a perineal rent of a serious character, Meigs, in the fifth edition of his work on midwifery, p. 54, said: "I defy any one to show me from my own practice a case of durable rent of the perineum."

By a case of durable rent of the perineum, Dr. Hamilton said he presumed that he meant one which would require surgical interference. It would not do to ignore this and say that Professor Meigs was an old practitioner, for his was not a theoretical idea, but a fact. But he was an accoucheur who very seldom employed instruments, and who, like his predecessor, Dewees, very seldom, if ever, resorted to anæsthetics.

DR. AUSTIN FLINT read a paper on

PERSISTENT FLATNESS OVER THE LIVER AS PROOF THAT ACUTE DIFFUSE PERITONITIS IS NOT ASSOCIATED WITH INTESTINAL OR GASTRIC PERFORATION.

Having referred to the paper which he read before the New York State Medical Society in 1882, in which he dwelt upon the significance of resonance over the hepatic region as an indication of the presence of gas in the peritoneal cavity from perforation of the intestines or stomach, he quoted at length the account of a case given by Dr. Alonzo Clark in his article on peritonitis in Pepper's System of Practical Medicine, by American authors. The patient, who was an iron-worker, aged fifty-nine years, died March 3, 1883. On the twenty-third of February, he had been attacked with severe pains in the region of the right iliac fossa. There was little fever and only slight acceleration of the pulse. His stomach was much disturbed, and the bowels were some distended with gas. Dr. Clark saw him February twenty-seven, in consultation with Dr. J. D. Elliott, the attending physician. The pulse was then 81; bowels much swollen and very resonant on percussion, the stomach still greatly disturbed. There was no green vomit, but much flatulency. Respiration was nearly or quite as much abdominal as in health, and there was a short friction sound in inspiration, but an entire absence of the sound produced by peristaltic action. There was no dullness on percussing over the iliac fossa, and no pain on pressure over any part of the abdomen. Dr. Clark says he was careful in examining the right fossa, for the first pain was there, and it was severe; but there was no physical sign by which perforation could be ascertained. Still, his mind dwelt on the probability of perforation, and he expressed his fears to Dr. Elliott regarding it. The respiration was of natural frequency. The bowels had not moved for two or three days. The history then goes on as follows:—

"The next day Flint was added to the consultation. The symptoms had changed but little; the pulse was 102; no pain, no tenderness, no peristaltic action; slight friction at one point only; the abdominal respiration was as marked as before. Frequency of respiration, 18; patient sleepy; pupils only slightly contracted. When we were in consultation I again

expressed my fear of perforation, but Flint expressed the most decided opinion as to its absence, because there was dullness to percussion over the liver. I had read his paper on the intrusion of gas between the ribs and liver in cases of intestinal perforation, and felt as if I were almost reproved for entertaining the thought without this physical corroboration. Thursday, March first, the stomach had become much more retentive; there was pain and no tenderness on pressure; pulse, 109; no friction sound, no sound of peristaltic action, no dullness on percussion over right iliac fossa, but resonant over the whole abdomen, excepting over the pubis; there the resonance was not clear; over a small space there was dullness; this was ascribed to moderate fullness of the bladder, and, as there had been difficulty in emptying it, nothing was said of it. The abdominal respiratory movements were the same as before. Friday morning, at 3 A. M., no marked change had occurred in the symptoms, but from this time onward there was a steady sinking of the vital powers. The pulse grew small and frequent, the hands became cool, the breathing more frequent, and without any sudden change or any new symptoms he died early in the morning. At the last visit there was no resonance of percussion of the liver." The autopsy was made Saturday, March third, at two P. M. There was now pretty free resonance over the liver, and the action to open the abdominal cavity was carefully made, with the aim of ascertaining whether there was air or gas in the peritoneal cavity. When a half-inch opening was made through the peritonæum, gas was forced out through it for some seconds with an unmistakable noise. Over the middle and upper portion of the intestines, which were not opened by this cut, there was a very thin film of false membrane; while two or three inches above the symphysis pelvis the section opened a collection of pus which extended downward into the pelvis. In this region a lump of fecal matter not indurated, and as large as a marrowfat pea was found, although the intestine was still unopened. Search was made for the appendix vermiformis, but at first it was not found on account of its shortness. It was found, however, pointing directly toward the median line of the body, and was short because a part had been separated from the rest by slough. The end of what remained was marked by a border, one-eighth of an inch deep, of a very dark-green gangrenous color. There was fully six ounces of pus, and it was completely bounded and shut in by adhesions.

Dr. Flint remarked in regard to this case that he could not agree with Dr. Clark in regard to the occurrence of early perforation. On the contrary, the inference which he drew from it was, that perforation did not result until just before the close of life, when it was produced by the sloughing of the appendix vermiformis; and the case, therefore, afforded, as it seemed to him, a striking proof of the correctness of the assumption that as long as there remained flatness or percussion over the liver, there could be no perforation. Dr. Flint then read the following notes in regard to the case, which he made at the time in his interlinear copy of his own work on the practice of medicine:

February twenty-eighth, visited Mr. Fletcher (50 to 60) with Drs. Elliott and Clark. Peritonitis had existed for three or four days. At this time hepatic flatness was normal. He was apparently doing very

well under full opiate treatment up to 3 A. M., March second. At that hour he was seen by Dr. Elliott, and there was no change for the worse. At 6 A. M., he was in collapse, and he died in the forenoon. Before the autopsy, percussion showed absence of hepatic flatness and great abdominal distension. A portion of the reniform appendix had sloughed away, leaving an opening. There was a local collection of purulent matter near the appendix, but elsewhere the appearances did not denote intense inflammation.

Conclusion: The patient was progressing favorably toward recovery, when sloughing of the appendix caused an opening, and death was by shock. The large intestine was collapsed; the small intestine much distended with gas. March 4, 1883."

Dr. C. S. Wood read a paper on

#### INTUSSUSCEPTION OF THE INTESTINES, WITH THE REPORT OF A CASE.

The case reported was that of a child eight years of age, who recovered after a long and tedious convalescence. The plan of the treatment adopted was, injections every three hours, of large quantities of warm water, while the patient's hips were elevated and the head depressed, one-tenth of a grain of calomel every hour as an alterant, sufficient morphia to relieve pain and procure some rest (usually one-eighth of a grain every three hours), ice *ad libitum*, milk and beef tea in small but frequent doses, and hot water cloths frequently renewed, over the abdomen. Sometimes a few drops of turpentine or of essence of pepper-utid were added to the warm water enemata. Afterwards the calomel was discontinued, and ipecac with aromatic syrup of rhubarb, given three times a day. Dr. Wood showed from statistics how extremely uncertain in its results was the operation of laparotomy for the relief of intussusception, especially in children, who easily succumbed to shocks, or inflammation produced by it.

THE PRESIDENT, DR. CHARLES A. LEALE, made some remarks on

#### A METHOD OF DIRECT LOCAL TREATMENT FOR DISEASES IN THE REGION OF THE ILEO-CÆCAL VALVE, AND ALSO FOR THE SAFE REMOVAL OF IMPACTIONS OF THE INTESTINES.

Having referred to the unsatisfactory results from cloacostomies by means of a long capillary needle, he exhibited a flexible rubber tube, which could be readily attached to an ordinary fountain syringe, and the extremity of which could be made to pass the ileo-cæcal valve, if this were required. He related a case in which there was infection of forces with an enormous accumulation of gas, and in which the tube passed fifty-nine and one-half inches into the intestinal canal, with the effect of affording complete relief. When it was deemed advisable to make applications to any part of the intestine thus brought within reach, bismuth or other suitable agents could be added to the water injected, and as a rule it was a good plan to insert a large rectal speculum before introducing the tube into the bowels.

Dr. H. M. Briggs presented some

#### INTERESTING PATHOLOGICAL SPECIMENS.

One of which was a heart with abundant vegetation on all four of its valves, a condition so rare that Dr. Briggs stated that he had never heard of another instance of it.

## Recent Literature.

*Antiseptic Treatment of Wounds.* By W. WATSON CHEYNE, M.D., F.R.C.S. New York: J. H. Vail & Co. 1885.

This little book (144 pages) is especially adapted to the use of medical students just entering upon their hospital experience. Beginning with a short review of the subject of septic diseases, it goes on to speak of the various antiseptic preparations and of the methods of disinfection. Finally the general principles and special methods of application of the antiseptic dressing, as used by Professor Lister, are carefully set forth. The following sentence, bearing upon a much-mooted point, is given entire: "It must always be remembered that Sir Joseph Lister carried out a septic treatment for years with great success without any spray; and if at the present time he were compelled for any reason to give up some one precaution, he would at once throw aside the spray as that one which is least necessary and which could be the most easily dispensed with. At the same time the spray is an immense convenience in many cases, more especially in abscesses, empyemata, in stitching up wounds, etc.; and it saves the necessity of applying a great deal of carbolic acid to wounds by irrigating them, with the consequent irritation and risk of carbolic-acid poisoning."

The manual cannot be too highly recommended to students; and they will find "Listerism" a very different thing from the slack methods they have seen employed under that name. The illustrations are numerous and good, and add greatly to the value and interest of the book.

*Clinical Lectures on Scrofulous Neck.* By T. CLIFFORD ALBUTT, M.D., and *On Surgery of Scrofulous Glands.* By T. PRIDGEN TEALE, F.R.C.S. J. & A. Churchill: London. 1885.

These two colleagues in the Leeds Infirmary, present respectively the medical and surgical aspects of their subject. Dr. Albutt regards scrofulous disease of the cervical glands as always secondary to some neighboring surface irritation, but thinks a tendency to the disease to be inherited as a "vulnerability of tissue."

As the pressure of caseous glands in the neck still further depresses the general health, the patient is rendered thereby less capable of resisting the advance of the disease to new glands. To break up this vicious circle he thinks that the thorough removal of the caseous material must be sought by surgical interference, and Mr. Teale relates many instances of the fortunate results of this treatment.

The idea of scraping out these glands is by no means new, and is in fact but one special application of the modern surgical treatment of tuberculosis; still every contribution towards the rapid propagation of correct surgical principles is of importance.

*Berlin as a Medical Centre: A Guide for American Practitioners and Students.* By HORATIO R. BROWN, M.D. Sandy Hook, Conn.: New England Publishing Co. 1885.

This unpretentious little volume (117 pages) is really what has long been desired by Americans, or we may justly say English speaking students who intend going to Europe for professional study. Its

main object is to present all desired information in respect to Berlin, but it incidentally gives valuable hints as to the advantages of certain of the other European medical centres. The work is full of those facts which most guide-books and descriptions do not mention, and gives the details of every necessary expense from leaving America until established in quarters in Berlin. Several schedules of prices for the entire cost of living in Berlin are given, from the most economical scale such as prevails in the student quarter where the tenant is a bachelor, to the comfortable, not to say luxurious suite of rooms of the married man, who desires all possible comforts for himself and wife.

A list of really good hotels and excellent boarding-houses is incorporated in the book, with prices and remarks as to quality of fare, rooms, etc. The reviewer can personally vouch for the correctness of a part of these from actual experience, and such an addition will no doubt be highly valued by the American student arriving in a strange city alone and unable to speak the language. To this is added a list of the libraries, museums collections, etc., of Berlin, which are not always easy to find or freely accessible to one entirely unacquainted with the ways of the German capital.

The advantages of matriculation and the method of obtaining it are described and the entire curriculum of the University course (medical) is given, as well as the "Ferien" courses, which are those most sought by our countrymen, the limited number of attendants allowing much greater freedom in personal examination and much more attention from the lecturer. The price of each course is given, so that the American student may fully map out his entire plan of study and form a tolerable accurate idea of the expense of his trip before leaving home. The principal subjects, surgery, gynaecology, etc., and the eminent teachers in them are briefly touched upon. Then follows a list of the hospitals, with location and days of visiting of each. To this is added a list of shops for the purchase of the various articles of personal or professional need while travelling, and finally a list of omnibus and street-car routes. The book finishes with a street directory and a map — which latter is the only typographically poor feature of the work.

The volume contains a large amount of just that practical kind of information which a stranger needs, and is for the English speaking physician desiring to make the best use of his time and his money, an indispensable companion. It is evidently the result of good faith and professional sympathy, as well as much effort on the part of the author, and is a reliable guide.

— Five young ladies, recent graduates of the New York Blind Asylum, have commenced the very laudable work of organizing a circulating library for the blind.

— One of the most novel and important of the practical philanthropies in the east end of London, a residence club of university men who have established themselves in the heart of Whitechapel in the aim to influence, by personal association and teaching, the degraded life of that locality, derives its name "Toynbee Hall," from its projector, Mr. Arnold Toynbee, a son of the eminent English artist.

## Medical and Surgical Journal.

THURSDAY, AUGUST 13, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

### RHEUMATISMS AND PSEUDO-RHEUMATISMS. — II.

AMONG the diseases to which the name rheumatism has been applied is one whose clinical characters are so well defined that it has by common consent been taken as a type of rheumatic affections, namely, acute articular rheumatism. But inasmuch as we have as yet no precise etiologic notion of this malady, and know no single criterion by which it is distinguished, so the mere fact of the existence of an arthritic disease is no proof that this arthritis is rheumatic. Certain arthritides are of traumatic origin; others are serofulous, syphilitic, pyæmic, etc. The joint affections of glanders are certainly of infectious nature, as are those which sometimes attend scarlet fever and small pox.

There is no doubt as to the legitimacy of the term rheumatism as applied to rheumatoid arthritis chronica. This disease has very close relations with acute rheumatism, often succeeding or being followed by the latter, always having a common parentage with it, and well-marked affinities with other diseases which are clearly of the family of rheumatisms. The specially predisposing conditions are inheritance, previous attacks of acute rheumatism, residence in cold, damp localities, exposure when the system is fatigued or debilitated to chilling blasts, to wetting, etc. It has been remarked that influences which provoke acute rheumatism in the young and robust, produce chronic rheumatism in the old and enfeebled. Charcot observes that there is a marked similarity between the changes occurring in chronic articular rheumatism and in the acute form, so that the lesions of the former may be regarded as but a higher expression of those which take place in the latter. Moreover, the visceral inflammation which complicates the chronic form are similar to those of the acute affection, although they are much less frequently witnessed.

For similar reasons rheumatoid arthritis has been assigned a place in the family of rheumatisms; this is especially true of that form known as Heberden's nodosities, "The pathogenesis of the rheumatoid arthritis," says Dr. R. P. Howard,<sup>1</sup> "is the subject of differences of opinion very like those existing in regard to acute

<sup>1</sup> Peppert's System of American Medicine, Vol. II, p. 92.

articular rheumatism. The weight of evidence is in favor of its diathetic relationship to rheumatism, and the doctrine of an arthritic diathesis and of the operation of the causes of the disease through the nervous system appears to be specially applicable to it, with less difficulty than to acute rheumatism, and the probability of a specific germ being the true cause is very remote. What seems to be necessary, in addition to the preceding, is that the causes shall be more persisting and oft recurring, so as to maintain a prolonged local irritation of the articular tissues, or that the neuro-arthritic diathesis shall be highly developed."

It is worthy of note that chronic progressive articular rheumatism (primitive asthenic gout, arthritis pauperum) has been somewhat violently separated from this group by Bouchard.<sup>1</sup> This disease, according to Bouchard, has more marked relationship to scrofula and phthisis (it attends on conditions of poverty, misery and debilitation) than to rheumatism or the rheumatic diathesis.

The various affections of the fibro-muscular structures included under the term muscular rheumatism (torticollis, pleurodynia, lumbago, rheumatism of the limbs, etc.), are so closely associated with the rheumatic diathesis, occurring so frequently in rheumatic subjects and under conditions known to give rise to typical rheumatism, that their place in the nosology of this family of diseases can hardly be disputed, at least while precise etiological data are lacking. As much cannot be said of those arthritides, solitary or multiple, which sometimes accompany or follow erysipelas, pyæmia and other infectious maladies; which, as before said, appear to be of specific, microbiotic origin, and have in their symptoms, course, lesions, and complications, nothing in common with typical rheumatic poly-arthritis.<sup>2</sup> These are clearly pseudo-rheumatisms, and so is that blennorrhagic arthropathy known as gonorrhoeal rheumatism.

The nature of this familiar affection of the joints has been long under dispute. It is to Swediaur in 1781 and to John Hunter in 1786, that we are indebted for the first descriptions of gonorrhoeal rheumatism. Rollet, in 1854, made an exhaustive study of its etiological conditions, and it was discussed in all its bearings at the meetings of the Société Médicale des Hôpitaux in 1866.<sup>3</sup> Some of the speakers said that this was a

true rheumatism which has blennorrhagia for its occasional provocative cause. Others affirmed that it was not rheumatism, but an infectious blennorrhagic affection of the joints. Others denied both the rheumatic and the gonorrhoeal nature of the articular affection, seeing in it only the result of a lesion of the urinary passages, which according to one hypothesis, provokes arthritides by neurotrophic reflex action; according to another, by simple infectious metastasis. We may sum up the present status of the question in the words of Bouchard: "It is probable that this form of arthritides is only exceptionally a true rheumatism. In fact the history of particular cases shows that the blennorrhagic arthritides have a particular physiognomy; that they are, in general, apyretic, ordinarily monarticular, obstinate; that they have the characters of plastic arthritides; that they tend to ulceration of the cartilages and fibrous ankylosis; that they are not at all influenced by salicylate of sodium; that the endocarditis and the pericarditis so frequent in true rheumatism are extremely infrequent in blennorrhagic arthritides; that, on the contrary, another complication rare in true rheumatism is here especially frequent, namely, iritis."

Recently Kammerer (Schmidt's "Jahrb., No. 1, 1885) claims to have found gonococci (the supposed specific microbe of gonorrhœa) in the joint exudation of a patient affected with blennorrhagic arthritis; these same gonococci were also found in the urethral discharge. It will be interesting to note whether micrococci of this character shall continue to be found associated with this form of arthritides.

There is a peculiar kind of rheumatism brought on by overwork, and often without the direct or indirect influence of diathesis, inheritance, or exposure to cold and wetting. It is called by Albert Robin "pseudo rheumatism of overwork."<sup>4</sup> M. Robin has well described this arthritic affection. It is by no means a pathological rarity, whether considered as a rheumatic or pseudo-rheumatic phlegmasia, and veterinary practice offers abundant examples of this disease. M. Philippe Hen, a veterinary surgeon, relates the case of a four years old courser which, after a prolonged race, was taken with erratic swellings of the joints and fever; in eight weeks the animal died of endopericarditis, as was proved by the autopsy. He has also witnessed formidable arthritides of ambulant character with cardiac troubles in colts too early put to hard work. This surgeon has also known excess of coitus in animals (another kind of overwork) to have a similar effect: young bulls after extreme genital fatigue in the service of cows have been taken with acute arthritides, which have in some instances been accompanied by endocarditis.<sup>5</sup> Bricou, in a recent number of the *Progrès Médical*, gives a similar instance of a male cat which had been a sort of feline Don Juan; the heart was found hypertrophied with right auriculo-ventricular insufficiency.<sup>6</sup>

That muscular fatigue may produce severe joint fluxions seems put beyond all reasonable doubt by

<sup>1</sup> *Maladies par relâchement de la Nutrition*, p. 315.

<sup>2</sup> Bouchard has shown that sometimes earlier fever induces the outbreak of an articular disease in no way distinguishable from acute rheumatism, but he also admits the existence of the pseudo kind (alluded to above), which is "an arthritide of an epidemic nature, benign in the vast majority of cases, but which may become very grave, and assume a purulent character. The latter cases alone deserve the name of scarlatinal arthritides." He shows that the same thing holds good with erysipelas, angina, chlorosis, and even blennorrhagias. The joint swellings which sometimes complicate chlorosis are often of a severe and obstinate kind, and unmistakably rheumatic. — *Vide Diseases of Old Age*, Am. Ed., p. 152.

<sup>3</sup> Recently the microbiotic theory of the etiology of rheumatism has again been brought prominently forward by Filleten and Fildes and Laufer. These writers base their views on the inductive study of several hundred cases of polyarthritides. Their assumption is that the virus is of organic nature, and that its abode is in the ground soil. That the maximum of cases observed occurs in January, the minimum in February, can be explained by the ascent of the microbes on account of the heated, hence rarefied and rising, currents of air prevailing in the houses in January, while in February on account of the continued heat and drying, a certain exhalation of the soil well with a dilution of contained germs, naturally ensues. Viardot of Leipzig goes a step further and believes in the essential contagiousness of rheumatism. (*Therapeut. Gazette*, July 15, 1885.) Bouchard, *Loc. cit.*

<sup>4</sup> *Gaz. Méd. de Paris*, June 20-27, 1885.

<sup>5</sup> *Gaz. Méd. de Paris*, 1885, No. 26.

<sup>6</sup> *Progrès Méd.*, 1885, p. 147.

cases which have been adduced by Trousseau, Gubler, Peter, Carrien, and others. Are these arthritides from fatigue or strain, of a rheumatic or pseudo-rheumatic nature? Doubtless in some instances true rheumatism has been so induced. A slumbering diathesis has been awakened, a "morbid opportunity," necessary for the development of an attack of typical rheumatism, has been created. In other cases the arthritic affection resulting from fatigue lacks conformity to the general type of classical rheumatic inflammation. The essential elements of the latter disease — the diathesis, even, — are wanting. M. Robin, in the monograph referred to, cites instances, and seems to us to have made out his case. One peculiarity of these "pseudo-rheumatisms" is their relatively inolent character and their painlessness. Not only "diathesis" and inheritance, but cold and humidity can often be excluded as causal factors. The swellings of the pseudo-form are fixed and persist in the joints primarily affected. The fever is mild, and the local symptoms have not that correspondence with the febrile symptoms which prevails in acute rheumatism.<sup>1</sup> In fine, the course of the pseudo-rheumatism is in no way influenced by salicylate of soda.

Robin thus attempts to explain the pseudo-rheumatism of overwork: "The first series of phenomena produced by overtaxing consists in modifications of the general exchanges, due to excessive activity of the nutrition of the muscles. A muscle in work gives rise to divers extractive matters and to lactic acid, the proportion of which increases in the ratio of the energy put forth. It is even upon this exaggerated production of lactic acid that an entire humoral theory of rheumatism has been built up, of which lactic acid is the morbid principle. Two things are lacking to this theory: First, the proof that lactic acid is really in excess in rheumatic patients; second, the explanation of the manner in which this acid can determine rheumatismal accidents. Let us then leave one side lactic acid, and retain only *en bloc* the excess of extractive matters thrown into the circulation as the result of a profound and continued trouble of the muscular nutrition.

"While the general nutrition is being thus modified, a second series of phenomena takes place on the part of the joints. There is heightened local activity of the exchanges (easily understood), which profoundly alters the synovia. Frerichs has made on this point some useful observations which may be thus summarized: In overdriven animals the synovia of the large joints undergoes important modifications; its quantity diminishes, at the same time that the fluid becomes thicker, denser and more tenacious; its richness in white globules augments and very notably, while the solid inorganic materials are lessened. Lastly, the synovine and extractive matters undergo an appreciable augmentation. Hence we have on the one hand a vice in the general nutritive exchanges, and on the other a local alteration in the nutrition of the overtaxed joints, whence results a *locus minoris resistentie*;

such are the sole pathogenic elements which it is in our power to set forth, and which, if they give a dim general idea of the process, are certainly insufficient to clear up all the details."

According to this view the organism is poisoned by its own waste products; the local fixation in joints which have been the seat of too much friction, of refuse elements of disassimilation (chiefly extractives), is the proximate cause of the arthritides. This is, as we understand it, substantially the theory of Bouchard, and does not differ much from the chemical theory of rheumatism itself. The darkness which still invests the subject of causation is well shown in these attempts at the explanation of familiar diseases. Recently a vigorous and plausible writer in the *London Lancet* has advanced a new doctrine of rheumatism, which he supports by a formidable display of chemical formulæ. "It is," he says, "the excessive formation of glycocholic and uric acid in the tissues that develop the symptoms of rheumatic fever, and salicylic acid cures the disease by combining with the antecedents of these bodies and preventing their formation."<sup>2</sup>

#### THE INTERNATIONAL CONGRESS.

It has been evident for some time that the prospect for a successful international congress in this country was very small. It is impossible to expect men of scientific attainments to cross the water to take part in a congress about which there is so much misunderstanding as in the present instance. It is exceedingly unpleasant to accept hospitalities in a house whose inmates are unable to agree as to the manner in which such hospitality shall be shown.

We are permitted to-day to print a letter from a medical gentleman, well known on this side of the water, which expresses the attitude which men, interested in the science and not at all in the politics of medicine, must necessarily take. The letter is addressed to Dr. J. Collins Warren, and is as follows:—

LONDON, 13 HARLEY STREET, July 25, 1885.

My Dear Collins Warren, — I have seen in medical papers, and heard through private sources, that a serious disagreement has occurred in respect to the organization of the ensuing International Congress in Washington. A few of those who had been concerned in organizing the London Congress, recently met to talk the matter over, for we feel that any failure which might attend the congress in the United States would be little short of a professional disaster. I do not myself think, and most here would share my opinion, that a congress from whose ranks some of our best physicians and surgeons have determined to withdraw, and whose members are to be further restricted to such as belong, either directly, or, by affiliation to one medical body in America, would be likely to be attended by many colleagues from this country.

Speaking from personal knowledge, an International Congress cannot be a success, unless taken up in the warmest and most self-sacrificing manner by all the principal men in the country where it is to be held. I was present at the meeting in Copenhagen, where the invitation to meet in America in 1887 was given, and after some discussion accepted. I am sure it was present to the

<sup>1</sup> This is well shown in Robin's thermometrical tracings.

<sup>2</sup> Latham in *London Lancet*, June 29, 1885: "Way does Salicylic Acid cure Rheumatism?"

mind of every one there that the invitation was one from the profession of America and not from any section of it, or any particular medical society in it. Otherwise I feel pretty certain Professor Virchow's invitation to meet on the next occasion in Berlin, would have been accepted.

Even now, it would appear to me wiser to have that invitation renewed, or to meet in some other place, than to have a meeting in America, from which so far as we may at present judge, many of the chief men on both sides of the Atlantic, would absent themselves. You are at liberty to use this letter as you deem fit.

Yours very faithfully, WILLIAM MACCORMACK.

It is not easy to see how the matter can be remedied so as to counteract the disagreeable impression already made upon foreigners. What the committee may be able to accomplish at its extra meeting in September can only be conjectured, but we are very sceptical as to their power to accomplish any good results. Certainly nothing can be expected from men who consider the numerous resignations that have taken place as manifestations of a conspiracy or as part of a game of bluff. We trust the editor of the Journal of the American Medical Association will be able to comprehend at least that the opinion represented by the above letter is not the expression of those who have deliberately undertaken to obstruct the work of organization."

## Correspondence.

### MEDICAL STUDY IN GERMANY. — FINKLER AND PRIOR'S FACILITIES.

ZURICH, July, 1885.

MR. EDITOR. — Our medical graduates when they go to Germany for continued study usually at once choose Berlin or Vienna, or both, for that purpose. I think this a mistake, and for two reasons: In the first place it is rarely the case that the student knows the German language sufficiently to be able, during the earlier portion of his stay, to follow a lecturer without great difficulty. This, I think, increases the force of the second, namely, material in the large schools is so plentiful that a young graduate cannot grasp the salient points and retain them in the hurried progress from organ to organ in a pathological course, and from patient to patient in large wards. In short, if the teacher, from press of organs or patients, has not time to cover the entire ground as it should be covered for a student, the latter under the difficulties arising from ignorance of the language, and from the almost bewildering profusion of material, naturally has not time either to comprehend or examine with anything like thoroughness.

Of course I do not mean to say that an American student should not study in Berlin and Vienna, but I believe he will go home with a far richer store of information, if he devote the first half of his stay to a smaller school where he may study without being embarrassed by the *Sturm und Drang* of the schools of the capitals and where, while he quietly, and therefore more quickly, develops his knowledge of the language, he at the same time is enabled to follow each branch of medical study with the thoroughness which arises from slower progress, and which is equally a result of more detailed explanation and demonstration on the part of the teachers, who, having less reason for haste than those of Berlin and Vienna, have more time for the needed instruction. If the student begin his course where in each lecture only one or two subjects are taken up and carefully treated, at its close, always supposing he knows the language, he has a clear understanding of the subjects in question. Whereas, in the same period of time, the teacher is obliged to touch upon twenty different matters,

can it be denied that at the end of the hour the student, instead of knowing something clearly, would be in the painful confusion resulting from understanding but little and that imperfectly of a score of similar subjects. Imagine, too, this confusion worse confounded by a tongue which he does not comprehend! This, I believe, is the mental condition of many of our young men during their first four, perhaps six months in Berlin or Vienna. Leaving America with but slight or no knowledge of the language, can a man be expected to advance very rapidly, excepting by means of what he sees, within the eight or nine months of session in the year of a German medical school? Subtract from his medical development, too, the time devoured by the thousand outside distractions of Berlin and Vienna and the year abroad shrivels still more. Many, I know, begin by devoting the first two months to the language, and this is eminently wise, indeed, is very nearly a *sine qua non* of merely a reasonable amount of advance in medical knowledge. The majority, however, fail to do this, and consequently too many return to America with a halting acquaintance with the language and likewise less scientific information than if they had not sacrificed time in a wrong method. One year abroad is really too short a period. Better half the loaf, of course, than no bread, but better the whole loaf if it can be procured. Our medical courses in general being none too long, it would always be advisable for the student to arrange a stay of at least two years. His German experience, in that case, would be valuable. Even if he go to Germany determined to devote himself to a specialty, it would be wiser to begin in a school of relatively circumscribed facilities and give at least two semesters to general medicine, for a specialist who has a good foundation of general medicine is twice the man he would be if he began at once upon his special study to the avoidance of a broad substratum. A young man not versed in the German language should in my opinion pursue the following plan: He comes abroad in June. His intention should be to begin his medical study in one of the provincial schools in which, he it fully understood, the teachers by a wise arrangement are all very able men. The student should settle during the summer vacation in some quiet town — Weimar, Eisenach, or Cassel — or still better in the vicinity of the school, and devote at least six hours daily to severe study of the language. If during the year previous to coming abroad he has made himself familiar with the principal parts of verbs and has gotten through the most foggy portion of the declensions, so much the better. He works faithfully six hours daily, talks whenever and wherever he can without regard to slips and blunders, listens to one sermon every Sunday, goes to the theatre every night if possible, and by the last of October he is passably prepared to listen to, say two, medical lectures daily of a practical sort, for example, clinical medicine and clinical surgery in which the eye aids the ear. Meanwhile he begins to read German medicine, especially upon the cases which he sees. By this means he quickly familiarizes himself with German medical terms. He increases the number of daily lectures according as he progresses in the language, and in the course of six weeks is probably ready to attend the entire course. As a bright and excellent type of the provincial schools I would cordially recommend that of Bonn. Following the general plan already laid down, the student should remain at the Bonn school until August 15th of the next year, when the summer semestre terminates. After a vacation, during which he should steadily pursue the study of the language, the student is ready for Berlin and Vienna. Now the fulness of material will not embarrass him, for he is familiar with the language, with German methods of teaching, and with medical expressions in that tongue. Moreover he has far more money at his command than if he had meanwhile been living in a large city, expenses of every nature being much less in Bonn. Hoping that my entire meaning has been made clear, I need say no more in regard to the student's course, but will rather confine myself to a sketch of the Bonn school to which I sincerely regret I did not give my first student year in Germany.

The instruction is carried on in various buildings, all of which are new and very handsome, and each of which possesses its comfortable lecture or operating room, the whole forming a large hospital. One building is devoted to clinical medicine, nervous diseases and laryngoscopy. Another to surgical teaching and operations. A third to midwifery and gynecology. A fourth to syphilitic and skin diseases. A fifth to anatomy, histology, chemistry, physiology, and the surgical operative course. This building is situated half a mile distant from the others, and is probably the finest and most convenient structure of its kind in existence. A sixth building is the well-arranged pathological institute, and stands within the hospital enclosure. Finally there is the building for infectious diseases. Pharmacy is taught, and eye and ear clinics are held in the old University building. Clinics on mental diseases are held by Professor Nasse in the noble hospital for the insane, just out of the city.

*Clinical Medicine* is taught by Prof. Hugo Rühle, a compatriot and student friend of Traube's, of whom he speaks with warm affection. Many interesting details did he give me of Traube's early struggles, of his poverty which was so bitter that Traube often had no dinner, but nevertheless was such an enthusiastic student that after receiving his degree, still being very poor, he was annoyed by any call from patients which took him away from his experiments. In his first studies upon the pneumogastric nerve his battery was of the oldest and most primitive character. At that time Schönlein taught in the Charité in Berlin, but so convinced was Traube of Schönlein's errors on certain clinical and pathological points that he would not attend the lectures of the famous clinician and laid down his arms only when Schönlein invited the young and almost unknown Jew to become his assistant. Traube had now attained such brilliant development in the newly-discovered art of auscultation and percussion and had made such important discoveries in clinical pathology and symptomatology that Schönlein found him indispensable, and thus Traube won entrance into the Charité.

Rühle was formerly in Breslau, afterward in Griefswald, from which school he was called to Bonn. Now, somewhat advanced in years, he is an excellent teacher, a fine diagnostician, and his whole heart is in his work. He holds a clinic every day in the week and lectures didactically once weekly. His material is more than sufficient, being sometimes drawn from the polyclinic, which is conducted by Dr. Prior in an ante-room, sometimes from the adjacent wards. Rühle's method is similar to that of the other clinical teachers, and one description will suffice for all. Upon a large cardboard each teacher has a full list of students who are called upon by name in the order of their inscription, a zero being set against the name of those who do not respond, and thus the marks for or against a student are taken into account at the close of a semester. Upon the medical roster this summer are sixty-eight names, upon the surgical seventy-five. The student in responding to the call comes down into the arena where is every possible facility for making, or failing to make, a diagnosis of the case before the class. Rühle likewise makes an examination of the patient, gives a brief lecture upon the disease, and clears up the diagnosis *per ratiocinationes*, and directs the treatment, seeking suggestions from the student, who is obliged to write a prescription upon the spot. Urine, blood, sputa and fluids from the cavities are examined before the class chemically and under the microscope, the clinical assistant aiding the student. Rühle makes a strong point of the Leyden crystals found in the sputa of asthma, believes them a principal cause of the spasms, directs the treatment with a view to their dissolution, and seeks for them in every case. During one clinic from one to four students enjoy this opportunity of making a diagnosis under Rühle's direction. Very frequently the class is taken into the wards for a similar purpose, and the clinic could not be better. Rühle has at home, as well as at the clinic, a very convenient chair which may be raised or lowered and the hinged back of which drops when the posterior portions of the patient's lungs are to be examined.

The clinic covers seventy-five minutes. The room, like all the lecture rooms in the Bonn school, is arranged with especial regard to light and the convenience of students, the back of each row of seats having a broad top which serves the comfortable purpose of taking notes, something which is generally forgotten at home, our students in the majority of schools being obliged to hold their note-books on the knee, a most fatiguing necessity. Every patient is examined and the entire range of symptoms and the organic results and effects are discussed with absolute thoroughness. This is a very striking characteristic of the school. It is remarkably thorough. No teacher leaves a subject until he has exhausted it, and the teaching is of the most cultured and scientific nature. In a school where material is too plentiful for the requirements of instruction, such thoroughness would be nearly unattainable. If a death occurs in Rühle's wards the autopsy, performed in the fine pathological building, occupies the first half of the ordinary clinical course, and at its termination the class proceeds to the clinical department, and there the professor sketches the disease of which the patient has died and with great care gives the points revealed by the necropsy, the students having already heard the protocol of the pathologist and examined the organs as they are removed from the body. If the autopsy be upon the cadaver of a surgical patient, the professor of surgery concludes his clinic thirty minutes earlier than usual in order to give students opportunity to attend the *post mortem* without interfering with the medical which follows the surgical clinic. An autopsy on a patient from the midwifery wards immediately follows the medical clinic.

In order to include in this letter mention of a matter of present and wide interest, I will allow myself temporarily to leave the clinical department to speak of the work of Professor Finkler.

With the assistance of Dr. Prior, Finkler, as you know, has taken strong grounds against Koch's assertion that the comma bacillus is peculiar to cholera Asiatica. Immediately after the discovery of the Koch bacillus, Finkler examined the feces of cholera nostras in cases occurring in Bonn. He discovered a similar bacillus. He at once started for Genoa, where the cholera was then raging. Prior accompanied him. They procured the Koch bacillus and compared it with the one they had discovered. On his arrival from Genoa, Finkler packed up his microscope and with no written preparation whatever, hurried to the Cholera Congress of last summer, then in session, where, as a heretofore unknown man he took the meeting by surprise in a brilliant address in which he announced his discovery of the comma bacillus in cholera nostras and asserted its similarity and kinship to the comma bacillus of cholera Asiatica. Finkler is gifted with the power of easy extemporaneous speech and fine language which made his address the more impressive. It aroused a storm of indignation and denial in the Berlin journals and among Koch's adherents. At first the existence of the comma bacillus in cholera nostras was denied even after search for it had been made. Later its presence in the feces of this disease was conceded, but Koch pronounced it unlike his bacillus, and it was claimed that it was *not* pathogenic. As you know, there has been and still is hot battle in the journals. Little by little various points have been yielded, and today Koch admits that the Finkler-Prior bacillus is pathogenic, and the only difference to be claimed between the two bacilli is that the bacillus of cholera nostras grows more rapidly in culture fluids than the Koch bacillus. This is acknowledged by Finkler and Prior, but they have found that after injecting the Koch bacillus into the intestines of a guinea-pig the bacilli which are obtained from the animal (for example, from the urine) grow in culture fluids as rapidly as, or even more so, than the bacillus from cholera nostras. For this reason, Finkler told me, he lances the bacillus of cholera nostras will eventually be shown to be a degenerate descendant of the Koch bacillus—one that has lost something of its original virulence, or differs in virulence because of its growth in a different soil. I will merely add that I have examined the two bacilli frequently, and have

watched their growth from day to day in various culture fluids, and I believe the position taken by Finkler and Prior with such scientific calmness to be indisputable. Allow me to close by giving you a careful translation of a *resumé*, taken from the proof-sheets of an extended pamphlet by these gentlemen, now in press, in which they state at they will gladly welcome any discussion of their views.

*The resumé.*—(1) We confirm the existence of Koch's comma bacillus in the contents of the intestines and in the dejections of patients who suffered from cholera Asiatica in Genoa in 1884.

(2) We have discovered the comma bacillus in the feces of cholera nostras patients; we have thus found them directly, by means of the microscope, and we were the first to breed them in pure culture fluids as well as the first to describe them.

(3) These two kinds of comma bacilli are vibrios which form genuine spirillae. In reference principally to their morphological rank, as well as in relation to the changes which they may undergo in form, the two vibrios are alike.

(4) The conduct of both in cultures agrees in most kinds of culture procedures. Differences manifest themselves only under very closely related conditions of culture surfaces and temperature, and declare themselves not so much by *absolute* as rather by far more *relative* peculiarities, namely, greater energy of growth and of vitality of the vibrio of cholera nostras.

(5) Of the physiological characteristics of these vibrios, we especially denote, and have already done this in an earlier paper, their marked capability of resistance against drying, against different temperatures and against putrefaction.

(6) We maintain the possibility of a condition of tenacity and consider it probable that this tenacity of existence

resembles that of one of the spores of some other micro-organism of similar formation.

(7) Both vibrios are pathogenic. (8) The pathogenicity of Koch's vibrio is greater than that of the *Finkler-Prior* vibrio; this also is only a question of *relative* difference.

(9) The pathogenic character does not manifest itself in all kinds of animals; far more, rather, a great number of animals possess immunity against both vibrios. They manifest themselves only under certain conditions. The animals which are susceptible to and the conditions which are favorable for the action of the bacilli are the same for both vibrios.

(10) The evidences of the disease called forth by the vibrios in the bodies of animals, possess a certain similarity to those of cholera in human beings; they are, however, not specific, but in the guinea-pig can be initiated by means of other infectious matters and by chemical poisons.

(11) The causative connection between the comma bacillus and cholera Asiatica is most probably shown by the constant presence of the bacillus, but is not to be considered as certainly proved by experiments on animals. The causal connection between the comma bacillus (discovered by us) and cholera nostras is probably shown on the one hand by the constant discovery of the micro-organism, on the other by the extreme similarity of the symptoms of cholera nostras to those of cholera Asiatica, as well as in the biological and pathogenic peculiarities of the two comma bacilli.

(12) The two vibrios can reach the blood after being injected into the intestines and are secreted in the urine. The sojourn of the Koch bacillus in the body of an animal creates an increase in the rapidity of its growth, so that thereby a still greater similarity between the two vibrios is attained in their demeanor in cultures. H. O.

were 31 deaths from consumption, diarrheal diseases 30, lung diseases 14, typhoid fever three, smallpox two, diphtheria and croup one, whooping-cough one. The death-rates were: at Geneva 10.1; Zurich 15.5; Basle 24.9; Berne 26.2.

Deaths reported 3,285; under five years of age 2,210; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 1,602, diarrheal diseases 1,602, consumption 282, lung diseases 127, diphtheria and croup 60, malarial fevers 34, scarlet fever, 31, whooping-cough 29, typhoid fever 28, measles 26, puerperal fever 15, cerebro-spinal meningitis 10, erysipelas six, smallpox one. From scarlet fever, New York, 10, Brooklyn, Baltimore, and District of Columbia four each, Cincinnati, Buffalo, and Holyoke two each, New Orleans, New Haven, and Charleston one each. From whooping-cough, New York 15, Baltimore and District of Columbia five each, Brooklyn, New Orleans, Buffalo, and New Haven one each. From typhoid fever, New York and District of Columbia seven each, Boston five, Baltimore and Lowell two each, Brooklyn, New Orleans, Nashville, New Bedford, and Malden one each. From measles, New York 16, Buffalo four, Brooklyn three, Boston, New Haven, and Nash-

ville one each. From puerperal fever, New York five, District of Columbia four, Brooklyn and Boston two each, New Orleans and Nashville one each. From cerebro-spinal meningitis, New York and Cincinnati three each, Buffalo, Worcester, Fall River, and Chelsea one each. From erysipelas, Baltimore two, New York, Brooklyn, District of Columbia, and Charleston one each. From smallpox, New York one.

Cases reported in Boston. measles 28, scarlet fever 19, typhoid fever 18, and diphtheria 18.

In 115 cities and towns of Massachusetts with an estimated population of 1,472,704 (estimated population of the State, 1,555,104), the total death-rate for the week was 23.83, against 23.81 and 17.33 for the two preceding weeks. In the 28 greater towns of England and Wales, with an estimated population of 8,996,446, for the week ending July 18th, the death-rate was 19.5. Deaths reported 3,321; infants under one year of age 1,090; deaths in London 1,616; acute diseases of the respiratory organs (London) 197, measles 143, whooping-cough 110, diarrhoea 291, fever 40, scarlet fever 34, diphtheria 23, smallpox (London 11, Sheffield and Sunderland one each) 13. The death-rates ranged from 11.5 in Halifax to 36.9 in New

castle-on-Tyne; Birkenhead 18.6; Birmingham 15.0; Bradford 12.2; Hull 13.4; Leeds 18.0; Leicester 23.8; Liverpool 22.1; London 2.06; Manchester 23.8; Sheffield 23.2. In Edinburgh 14.2; Glasgow 22.1; Dublin 27.2.

For the week ending July 18th in the Swiss towns there were 35 deaths from consumption, diarrheal diseases, 18, lung dis-

eases nine, smallpox four, diphtheria and croup one, typhoid fever one. The death-rates were: at Geneva 10.0; Zurich 7.8; Basle 24.9; Berne 27.3.

The meteorological record for two weeks ending August 1st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

A CASE OF LABOR IN A WOMAN WITH SPONDYLOLISTHETIC PELVIS.<sup>1</sup>

BY F. H. LOMBARD, M.D.

Mrs. Nellie O., age, twenty-six years. Primipara. Of Irish parentage, born in Boston, where she has always lived. Father died of pneumonia. Mother, who became insane when Nellie was two years old, has been in the asylum at Worcester ever since.

Learned to walk during second year. When three years old while playing in the street was run over by a horse and carriage, the wheels passing directly across her body. Whooping-cough the only disease she has ever had.

Catamenia appeared at fourteen years; always regular; every four weeks; five days; moderate; considerable pain and discomfort always the day before her sickness appears.

I first saw the patient in October, 1883, when she was suffering from tonsillitis. She reported herself to be five months advanced in her first pregnancy and asked if I would take care of her during her confinement. Her dwarfed stature attracted my attention and obtaining her permission to measure the circumference of the pelvis, this was found to be 69 cm. (27½ inches), the normal being 90 cm. (35½ inches). Although a primipara whose abdominal walls had never been previously distended, the abdomen was so pendulous that in the upright position the umbilicus was on a level midway between the hips and the knees.

Her husband was told the risk there would be in advising the pregnancy to go on to term and was advised to have his wife enter the hospital.

To this she objected, but promised to consider the matter and let me know. An abdominal belt with shoulder straps was improvised and, as subsequently learned, this was worn until within a few days of confinement.

The next day I visited the patient again and took accurate internal and external measurements of the pelvis. Two weeks later, having heard nothing from Mrs. O., I called to see her but found the family had disappeared, no one knew where.

March 3, 1884, four months later, I was summoned to the house in the rear of number 378 North Street, where I found Mrs. O. in labor.<sup>2</sup> It was then five o'clock in the afternoon and she had been having irregular pains since early morning. Examination showed an os the size of a silver quarter dollar, membranes intact, head presenting, and not yet engaged in the pelvis, though with difficulty moveable. Fetal heart could not be heard; back of fetus to mother's right. Mother's pulse 108, fairly strong. Temperature 99.3° in the axilla. The pains which had been strong and frequent all the afternoon were beginning to tell upon the mother, but during the hour following my visit, they had little or no effect upon the os. Fifteen grains of chloral were given by the mouth and the dose repeated twice at intervals of twenty minutes.

Mr. C. E. Taft, at that time a third year student, was sent for, and to him and to Mr. Howe I am indebted for valuable assistance in the subsequent care of the case. The failure of the strong pains to dilate

the os, being evidently due to the great anterior obliquity of the uterus which kept both the fetal head and the bag of waters from entering the os as a wedge; the patient was put to bed on her back, and from this time until the head had engaged in the pelvis (a space of twelve hours) the uterus was held in position and every effort made with each succeeding pain to force the head into the pelvic cavity.

During the night and following morning progress was slow but steady. The patient suffered a good deal from nausea and vomiting, but as her pulse, temperature, and general condition continued favorable there seemed to be no indication for active interference. Small quantities of brandy and tea were given at intervals through the night and morning. Hot carbolic (1 to 60) vaginal douches (110° F.) were given from a fountain syringe three times during the morning, with a view to assisting the dilatation of the cervix and to reducing the excessive edema of the anterior lip which progressively increased with the advance of the head. At 11.10 A.M., when the os was about the size of a trade dollar, the membranes were accidentally ruptured during an examination. Two hours later, the os being fully dilated, forceps were applied (the patient refusing ether) and in thirty minutes a fully developed male child, stillborn, was delivered. All attempts to resuscitate the child failed; length 50½ cm.; weight not taken. The uterus contracted well after delivery, but there was considerable hemorrhage from the lacerated cervix and perineum, requiring the application of ice.

Five silk sutures were taken in the perineum which had been deeply torn to the right of the median line, the tear extending into the sphincter. Convalescence was slow, the patient not sitting up until the fourteenth day, and recovering her usual strength only at the end of two months. The pulse during the first fourteen days averaged 107, reaching its maximum, 132, on the evening of the third day.

The temperature did not fall below 100° F. during the first fortnight, averaged 101.5°, and reached its highest point, 103.2°, on the twelfth day.

Incontinence of urine lasted until the fourth day; incontinence of feces until the fourteenth. Tympanites was a troublesome symptom until the fourth day, although a large amount of flatus was involuntarily expelled with every change in position.

The lochia were scanty throughout, chiefly purulent and stopped altogether on the sixth day; they were never offensive.

The uterus contracted slowly during the first four days, swinging from side to side high above the pubes, apparently affected by every change in position of the flaccid bowel. After the second involuntary defecation and the coincident disappearance of the tympanites on the fourth day, the uterus sought the middle line and its involution then progressed normally.

The body of the uterus was never abnormally tender to the touch, and by the fourteenth day the fundus had disappeared below the pubes. Extensive sloughs which subsequent examination showed to have been parts of the bruised and lacerated cervix came away from time to time with varying amounts of pus in washing out the vagina.

The upper perineal stitches, sloughed through on the third day, while the lower ones, removed on the seventh, showed integumentary union in the lower half of the wound.

<sup>1</sup> Read, by invitation, before the Obstetrical Society of Boston, April 11, 1885.

<sup>2</sup> This was exactly 284 days from the afternoon of her marriage (May 26, 1883) on which date her last catamenia ceased.

On the eighteenth day after delivery vaginal examination revealed: Partially healed perineum; about an inch and a quarter above the anus the tip of the little finger introduced into the rectum appears in the vagina. Uterus low in pelvis, slightly anteverted, firmly contracted. Deep, left lateral laceration of cervix with extensive loss of substance.

The moderately high and even course of pulse and temperature is consistent with the pretty extensive suppuration which occurred, and shows that the pus had free outlet and that there was at no time septic infection.

*Treatment:* Consisted briefly of liquid and farinaceous diet, free use of brandy and tonic doses of quinine throughout. Ergot was given several times during the first three days, and opium was required once or twice. Turpentine in stipes and internally was given to relieve the tympanites.

Hot carbolic vaginal douches (1:60 at 110° F) were given twice a day, and a wad of absorbent cotton soaked in carbolic was kept constantly at the vulva, the swollen entrance to which was dusted twice a day with Pulv. Iodoform.

Nothing could have been more unfavorable than the hygienic surroundings of this patient.

A family of six adults occupied two small rooms and a closet in the second story of a wooden tenement in one of the worst slums of the city. A row of stinking privies resorted to by the whole neighborhood as well as by passers-by, stood in the yard below, — a stench-centre sufficient to contaminate the whole district. The lying-in room, into which no ray of direct sunlight ever fell, opened off the kitchen, and nearly all of the available space in it was occupied by the bed. To make matters worse, though with a view to making them better, the landlord had sent the plumbers on the day of Mrs. O.'s confinement to clean out the trap under the kitchen sink, in the midst of which process I found them on my first visit.

With this germ-laden condition of the atmosphere, and with an extensive suppurating surface ready for infection, we must either agree with Winckel (who does not hesitate to place a healthy, recently-delivered woman by the side of a case of puerperal septicæmia) that the atmosphere plays an insignificant rôle as a carrier of infection, or we must admit that the much-abused, vaginal douche occasionally performs an important service in prophylaxis.

A month after her confinement I again lost sight of the patient and did not see her again until February, 1885, when she came to the Dispensary complaining of backache, amenorrhœa and distress at each menstrual epoch.

Faces had continued to be expelled through the vagina for six weeks after her confinement. Since then defecation had been natural. Examination by the rectum showed complete closure of the recto-vaginal fistula, a circular cicatrix, the size of a three-cent silver bit, marking its site in the posterior vaginal wall.

By the vagina very little could be seen or felt of the left half of the vaginal portion of the cervix; the uterus, normal in size, lay in the position of right latero-retroversion, and was slightly adherent. Last week Dr. C. M. Green kindly examined the patient with me at the Boston Dispensary, when the above condition of the pelvic organs was corroborated and the following measurements taken; except that they

are more complete they do not differ essentially from those taken during pregnancy.

#### SUMMARY OF THE CASE:

Labor at term in a primipara 26 years old, with Spondylo-  
listhetic Pelvis.

Duration of { First stage, 2  $\frac{1}{2}$  hrs.  
Labor 23 hrs. { Second " 50 min.  
                          Third " 40 min.

Delivery with forceps of a fully developed, dead, male child. Extensive laceration with subsequent sloughing of cervix. Deep tear in the perineum which partially united, leaving a recto-vaginal fistula that subsequently healed of itself. Slow convalescence with moderately high and uniform temperature and pulse.

#### DIAGNOSIS OF THE SPONDYLOLISTHETIC PELVIS.<sup>3</sup>

This form of contracted pelvis is rare. According to Schroeder,<sup>4</sup> nine such cases have so far been reported in which there was obstruction to delivery. In seven of these the peculiar deformity was confirmed by autopsy.

The chief feature consists in the separation of the body of the last lumbar from the first sacral vertebra and the consequent sinking of the lumbar spine into the pelvis, so that the inferior surface of the last lumbar rests on the anterior surface of the first sacral vertebra. The anterior surface of the last lumbar vertebra is directed downward; that of the fourth, third and second lumbar vertebra form an arch, the most prominent part of which being nearest to the symphysis, takes the place of the normal promontory. The result of this displacement is a considerable shortening of the antero-posterior diameter of the inlet of the pelvis.

The gradual sinking of the vertebrae is accompanied by an atrophy of the intervertebral cartilages and by a bony union between the lumbar and sacral vertebrae. The weight of the body conducted through the spine is now transmitted to the anterior surface of the sacrum instead of to its base, which tends to throw the pelvic centre of gravity forward. This is compensated for invariably by lessened inclination of the pelvis, the anterior portion being slightly tilted upward. The backward pressure upon the base of the sacrum forces

<sup>3</sup> Lusk, pp. 194-195.

<sup>4</sup> Lehrbuch der Geburtshilfe, S. 556, Schroeder, Loc. cit.

the posterior iliac spines wide apart while the apex of sacrum is thrown forward thus encroaching on the antero-posterior diameter of the outlet.

The traction upon the ileo-femoral ligaments approximates the tubera ischi, which, with the lateral displacement of the ilia due to the forcing back of the sacrum, results in a narrowing of the transverse diameter of the pelvis that becomes more marked as the outlet is approached.

Thus we have antero-posterior narrowing beginning above and extending below the inlet of the pelvis, together with a narrowing of the transverse

transverse processes induced by traumatism, or by traction upon the articular ligaments sufficient to produce luxation (as from the too early carrying of heavy weights). In the case here reported the trouble dated apparently from the accident which occurred in the third year.

#### DIAGNOSTIC SIGNS.

Breisky<sup>6</sup> calls attention to the peculiar figure of persons with spondylolisthetic pelvis. The thorax and extremities are normal while the abdomen is unusually short and appears to have sunk between the prominent iliac crests.<sup>7</sup> The pelvic inclination is lessened, the

points of the ilia are wide apart and the gluteal muscles abnormally steep.

The point of division of the abdominal aorta into the common iliac arteries is displaced downward by the descent of the lumbar vertebra and lies within easy reach of the examining finger introduced into Douglas' cul-de-sac. The pulsation of these vessels whose abnormal situation is held by Schuchardt to be of extreme diagnostic value, could be distinctly felt in the case reported.

Marked cases of rachitis may result in the same prominent lumbar hump and descent of the vessels.

<sup>6</sup> Breisky, *Archiv. f. Gyn.*, 1890, 18, 1, 100.  
<sup>7</sup> See accompanying plates.

diameter beginning in the cavity and becoming more marked toward the outlet (compare measurements and plates.)

#### ETIOLOGY.

The primary cause of this deformity is the operation of the articular surfaces of the last lumbar from the first sacral vertebra. This may be brought about by fracture of the transverse processes; either of the

into the pelvis. The differential diagnosis is easily established by absence in cases of true spondylolisthesis of signs of rachitis elsewhere, and by the fact, attention to which was first attracted by Breisky<sup>2</sup> that in pelvic deformity due to rachitis, the sacral lateral masses pass outward from the projecting promontory, while in spondylolisthesis one can feel at the pelvic inlet only the rounded prominence of a single vertebral body without laterally expanded wings.

#### PROGNOSIS.

The prognosis is bad in comparison with that in pelvis contracted to an equal degree from other causes; because the deformity begins above and extends below the pelvic inlet instead of being limited to a comparatively short space.

#### TREATMENT

Generally consists in the induction of abortion or at term in Cæsarean section. Premature delivery was beyond all question the proper treatment to have followed in this case, and labor would have been induced at the seventh month or soon after, had not the patient disappeared from sight. Pregnancy having advanced to term, the choice lay between Cæsarean section, turning, delivery by forceps, and craniotomy. The mother's safety certainly did not demand Cæsarean section and the operation would have been justified only for the sake of securing a living child.

Turning would have been practicable, the patient having been seen before the head had engaged in the pelvis and the membranes being still intact.

The operation would, however, have been difficult, owing to the extreme ante-flexion of the uterus, and although to be preferred to the application of high forceps in the interest both of mother and child, it was by no means clear to me that it was my duty to turn, rather than to wait, and while watching the case carefully, give nature a chance.

I think the result justified my choice of the latter action. The deformity being one which involved not merely contraction at the inlet, but contraction beginning above and extending to the outlet, even had version been effected, the chance of delivering a living child would have been, I think, very small, while the dangers to the mother, from laceration of the soft parts, would have been as great, and those of septic infection greater than in application of forceps to the head after it had entered the cavity of the pelvis.

As for perforation; the obstruction to delivery was not sufficient to demand it, and as the death of the foetus was not absolutely certain, perforation would not in this case have been justifiable.

Of the nine cases quoted by Schroeder:—

One died undelivered. In four Cæsarean section was performed. Three of these patients died from the operation; the fourth (Pardethorn's case) survived a first Cæsarean section and having become pregnant again, succumbed to the second operation. In two, craniotomy was performed, and in two, artificial abortion was induced. Total, seven deaths; two recoveries.

So far as I know, this is the first case of spondylolisthesis of the pelvis of obstetric interest reported in this country.

### CONSAANGINEOUS MARRIAGES: THEIR EFFECT UPON OFFSPRING.<sup>1</sup>

BY CHARLES F. WITHINGTON, M.D., OF BOSTON.

THE subject of this paper is of interest alike to the physiologist and to the practitioner of medicine, who is constantly liable to be called upon for his opinion as to the desirability, or more often as to the safety, of prospective marriages between relations. The great practical importance of correct views upon this matter has seemed to me, therefore, to justify still further investigation of a topic on which, although much has been said, little has been settled.

The traditional belief, held still by a large majority of the laity and by very many of the medical profession, has been given physiological expression by no one with greater clearness than by Dr. Devay. He says<sup>2</sup>:—

"The objection to consanguineous marriages is not . . . the perpetuation in families by means of inter-marriages of maladies susceptible of hereditary transmission, as certain forms of temperament, certain organic predispositions, like narrowness of the chest or other vices of formation. It is evident that the condition of consanguinity in itself adds nothing to the chances of morbid inheritance which, depending upon the health of those marrying and of their respective ancestors, have the same source in every sort of marriage. We charge upon unions between relatives of the same stock, the production, by the sole fact of non-renewal of the blood (*non renouvellement de sang*), of a specific cause of organic degeneration fatal to the propagation of the species."

Now this statement is very explicit, to the effect that besides the ordinary laws of inheritance which may affect off-spring for good or for bad, there is in marriages of relations a specific degenerative influence, due to the mere fact of "non-renewal of the blood." If this be true, it follows that the operation of this influence will be equally potent and baneful when the persons united are healthy as when they are diseased. And there should be discoverable among the off-spring of such unions a conspicuous deterioration, out of all proportion to those other hereditary influences whose potency is so well established. Indeed it is difficult to see why, if this supposition be true, we should not find some evidence of degeneration present as the rule in all the persons born from marriages of relations, inasmuch as in all these cases by the hypothesis this specific cause of degeneration is present. Whether this is the fact, has been made the subject of inquiry by many investigators, but with results so utterly diverse as to leave the student more bewildered than ever, and to suggest that in no field of investigation has the statistical method more pronounced limitations than in this. In a paper like the present we can only allude in the briefest manner to some of the most important collections of cases illustrating the opposite views on this question.

Dr. Beniss<sup>3</sup> collected thirty-four cases of consanguineous marriages. Seven, or 20.5 per cent were barren. One hundred and ninety-one children were born; an average of 5.6 children per marriage, barren and fertile. Of the one hundred and ninety-one children, fifty-eight died young; fifteen of them from con-

<sup>3</sup> *N. A. Med. Chirurgical Review*, January, 1857.

sumption. Of the surviving one hundred and thirty-four, thirty-two are said to be "deteriorated, but without absolute indications of disease." A large number of diseases and defects are ascribed to forty-seven of the remainder, and only forty-six are described as healthy.

Dr. Bemiss also made a report to the American Medical Association<sup>4</sup> the following year, in which he collected eight hundred and thirty-three consanguineous marriages, producing three thousand nine hundred and forty-two children, being 1.6 children per marriage, 28.7 per cent are put down as defective, 3.6 per cent as deaf mutes, 2.1 per cent as blind, 7 per cent as idiots, 2.04 per cent as insane, 1.5 per cent as epileptic, 7.6 per cent as scrofulous, and 2.1 per cent as deformed; 22.4 per cent are recorded as "having died young."

Dr. Howe<sup>5</sup> collected in the same year, from statistical tables in Massachusetts, seventeen cases of marriage of kindred. "Most of the parents were intemperate or scrofulous; some were both one and the other." These unions produced ninety-five children, of which forty-four (nearly 50 per cent) were idiots, twelve were scrofulous or puffy, one deaf and one a dwarf.

Dr. Arthur Mitchell,<sup>6</sup> Deputy Commissioner in Lunacy for Scotland, found among one hundred and forty-six children born from forty-five consanguineous marriages (thirty-seven of them being fertile), 5.5 per cent idiots, 3.1 per cent imbecile, 7.5 per cent insane, 1.1 per cent epileptic, 3.0 per cent paralytic, 1.1 per cent deaf mutes, 2 per cent blind, 15 per cent "consumptive, scrofulous or manifestly of weak constitution." A total, as he says, of 61 per cent of the marriages producing children in some way injuriously affected.

M. M. Cadiot,<sup>7</sup> Devay<sup>8</sup> and Boudin<sup>9</sup> have also published statistics showing the evil effects of marriages of kin among their own countrymen.

If we now turn to the other side of the account we find equally positive results. In the first place M. Bourgeois<sup>10</sup> gives us the history of his own family, descended from a consanguineous union in the latter part of the seventeenth century. Eight of the marriages are those of consins and the remainder, some sixty in number, all feel the influence of consanguinity. Yet only one union in the entire number has been infertile, and here the fault was undoubtedly in the wife, a woman of alien stock, while the husband was three generations removed from the nearest marriage of kin. In one branch there are four marriages of consins in five successive generations, one of them being of double first consins. Yet the children of this last union, being four times of kin, are six in number and are all well and bright save one, the victim of a traumatic accidental injury. The health of all the two hundred descendants is excellent, except in one family of grandchildren and great-grandchildren from the double consin marriage, where a scrofulous taint has crept in.

Seguin<sup>11</sup> gives the particulars of ten marriages of kin in his own family, two of the number being of

uncle with niece and the rest of first consins, from which sixty-one children were born, most of whom lived to grow up, not a single one showing deaf-mutism, hydrocephalus, stammering or polydactylism.

Dally<sup>12</sup> gives a case of continued intermarriages between two families, all being of first consins save two which were of second consins. This has continued for five generations with an average of three or four children per marriage. The total number of branches direct and collateral is one hundred and twenty to one hundred and forty, though quite a number of the family have been celibates. There has been no case of idiocy or deaf-mutism, and but one of insanity, and that in an old woman.

M. Voisin<sup>13</sup> found in the isolated commune of Batz forty-six consanguineous marriages. Five were between first consins, producing twenty-three children; thirty-one were between second consins and produced one hundred and twenty children; and the ten remaining unions gave birth to twenty-nine children. All were healthy and free from deformities of every kind. The community consists of some 3,300 souls, and has always been very much isolated. They are simple, intelligent and moral, and not a single case of mental disease, deaf-mutism, albinism, retinitis pigmentosa or any malformation could be found, though the inhabitants had closely intermarried from time immemorial.

These two classes of observations, so diametrically opposite in their conclusions, cannot both be accepted as fairly representing the facts. If, now, we look for a moment at the testimony with regard to specific constitutional defects, given in most part by men agreed as to the generally unfavorable effect of consanguineous marriages, we find equally unreconcilable discrepancies. Take the point of idiocy, for instance. Dr. Howe's figures show that 41 per cent of the children of persons related to each other were idiots, while Bemiss, in one set of his cases, found the idiots to compose 7 per cent of all the children born, and in another set to amount to only 2 per cent.

In the matter of deaf-mutism, we have the statement of Dr. C. A. Cameron,<sup>14</sup> based upon the Irish census of 1881, that of the 5,136 deaf mutes enumerated in that country, 135 (being 2.6 per cent of the whole) were the children of first consins. Yet Dr. Fitzpatrick, in the very discussion which followed the reading of Cameron's paper, asserted that in his experience almost every case of deaf-mutism occurred in persons born from parents who were related.

Huth, in his interesting work, to which I am indebted for one or two of the foregoing references, has collected the results published by some fifteen investigators as to the proportion of deaf mutes consanguineously descended,<sup>15</sup> and finds the percentages given to vary from a maximum of 30.4 to a minimum of 3.2, — a range so great as seriously to invalidate the figures.

One or two discrepancies in the results of individual observers deserve to be noted. In this same matter of deaf-mutism Boudin says,<sup>16</sup> that estimating the danger of a deaf mute being born from an ordinary marriage as one, in a union of consins it is eighteen, in one of uncle with niece it is thirty-seven, and in one of aunt

with nephew seventy. If this defect is due to the mere fact of consanguinity in the parents, its danger should vary directly as the nearness of the relation. But an aunt and nephew are no nearer than an uncle and niece. Why then should there be twice as much danger of deaf-mutism in the one case as in the other?

Again, it appears from the tables of Bonis,<sup>17</sup> that the percentage of the "defective" in the children of third cousins is actually greater than in the offspring of second or even of first cousins. But it is manifestly absurd that effects due to the mere fact of consanguinity should be more disastrous where the degree of relationship is the eighth than where it is the fourth,—in persons having only six per cent of the blood of a common ancestor than in those having 25 per cent.

Impressed by the unreliability of many of the statistics published upon this subject, I have gathered what cases I could hear of, as a contribution to the study of an important subject. Before laying the results before you, I may be allowed a word regarding some of the difficulties of the problem. In the first place, all cases collected in this way are almost of necessity selected ones, and I cannot flatter myself that my own form an exception to the rule. In recalling instances of consanguineous marriage, persons are apt to remember only those which have been made conspicuous; and nothing is more conspicuous than defectiveness among the offspring. The opposite kind of selection, that is, the suppression of unfavorable cases, is much less common, for if an individual should keep back an unfortunate page of his family history, his neighbors will know and report the fact, even while they become obligations of the uneventful commonplace cases. It is the ill news that travels fast and far. At least three of the unfavorable cases in my list I heard of from multiple sources.

In judging of the results, moral factors have to be allowed their just value. Intemperance, which was present for instance in most of Dr. Howe's cases, the depraved morality attendant on incestuous unions, the luxury and dissipation prevalent in many royal and noble families, the sloth and shiftlessness of many isolated communities, should often bear some at least of the responsibility that is put upon consanguineous marriages. Testimony is sometimes colored by religious prejudices in those who hold allegiance to the canon law. When one reads over the forty or more abnormalities ascribed to the intermarriage of kin, as in the cases collated by Huth, and finds among them such diseases as porriasis and whooping-cough, he is forced to believe that the narrator was run away with by his hypothesis.

The great difficulty, after all, is in cases where the children of relations display any taint or defect, to exclude the influence of morbid inheritance. The influence of this factor is very evident in some of my own cases, and is abundantly sufficient to account for the evil results had there been no relationship between the parents.

In regard to inheritable diseases in the parents, I have often been unable to gain information. But no one I think can deny that simple heredity may have borne an important part in most of the cases. Whether it will account for all the facts is a question which we must leave to fill later. Now one very important conclusion follows, namely, that a case where no evil result follows a consanguineous marriage is of more value as evidence against the intrinsic harmfulness of

such a union than an unfavorable case is for its harmfulness. For in the former instance at least we know that consanguinity was harmless; in the latter we know that *something* was harmful; it may have been consanguinity or it may not. In other words, the effect being removed there can have been no efficient cause, not even consanguinity; the effect being present, the cause must be looked for among *all* the antecedents, not consanguinity alone. If then there were an equal number of good and bad results from such unions, the evidence would preponderate in favor of the harmlessness of the element of consanguinity. I have tabulated one hundred and eight cases of consanguineous marriage, collected from various sources, professional and non-professional. (These tables will be appended to the present article.) None of the cases, so far as I am aware, have been published before. In eighty-six instances the relationship was that of first cousin; in four, first cousins once removed; in thirteen, second cousins; in one, third cousins; in one, cousins, degree not specified; in one, uncle and niece; in two cases the parents bore the relation to each other of brother and sister.

I have classed as healthy only those individuals who appeared to be free from any congenital defect or disease, and who had an average degree of intelligence and bodily well-being. On this principle among the non-healthy are included all who suffered even from such slight defects as stammering and strabismus; all who were "under par" in intelligence or "not strong"; all who had phthisis, even though the disease developed late, and the individual was for thirty or forty years considered well; all who died in infancy, unless there was evidence that the death was from some acute disease and independent of any possible inherited taint.

With this somewhat stringent interpretation of the word, I find three hundred and twelve "healthy" children out of a total of four hundred and thirteen, the direct offspring of consanguineous marriages,—the per cent. being about 75].

The non-healthy individuals comprised:

Deaf Mutes, . . . . .	12
Insane, . . . . .	7
Idiots, . . . . .	13
Blind, . . . . .	3
Died of Consumption, . . . . .	15
Nervous, . . . . .	5
Of less than average intelligence, . . . . .	8
Died in infancy, . . . . .	16
Not robust, . . . . .	6
Hermaphrodite, . . . . .	1
Died of Meningitis, . . . . .	2
Cross-eyed, . . . . .	2
Still born, . . . . .	2
Deaf (not congen.) . . . . .	2
Stammerers, . . . . .	2
Myopic, . . . . .	2
Deformed, . . . . .	2
Epileptic, . . . . .	1

Total, . . . . . 101

Among these one hundred and one persons were also duplicate defects, as follows: 2 cases of talipes varus; 1 case of somnambulism; 1 case of myopia; 1 case of polydactylism; 1 case of epilepsy; 2 dwarfs.

In all of the one hundred and eight marriages, save five, there was issue. In one of these infertile cases

there was mechanical impediment present in the wife, and in another the marriage has lasted only two years. In fifty-seven cases only, is it known that husband and wife lived together the average period of fertile married life, which I have assumed at twenty-five<sup>12</sup> years. The total number of children born from these fifty-seven unions, only two being infertile, is two hundred and eighty-two,—an average of about five children per marriage.

In seventeen of the marriages the contracting parties were one or both descended themselves in the first or second generation from consanguineous unions; one of them was blind, another a deaf mute, child of a deaf mute. Fifteen of these marriages have thus far been fertile, with a total of sixty-eight children, of whom forty-eight, or 70½ per cent, were "healthy."

The remaining twenty comprise two idiots, three below average intelligence, five who died of phthisis, one of meningitis, five who died in infancy, one hemiparalitic, one scrofulous, two not robust.

Only nine of these consecutive consanguineous marriages are known to have lasted through the complete period of conjugal fertility. These nine produced fifty children, an average of 5.5 each.

The statement has often been made, as for instance by Guipon,<sup>19</sup> that when sterility does not attend the marriage of relatives it yet shows itself in their offspring. Our tables give the facts regarding one hundred and twenty-eight marriages in which one or both parties were descended in the first or second generation from consanguineous unions, but themselves married persons not related to them. Of these one hundred and twenty-eight unions, some of which have lasted but a short time, one hundred and ten, or 86 per cent, have thus far proved fertile. The number of children cannot be told, because my information in many cases is simply that there was issue. Interpreting that expression to mean only one child, there are, at least, three hundred and seventy-two children. In forty-seven of the cases only is there evidence that the union has lasted twenty-five years, and at the same time a definite record of the number of children. These forty-seven marriages give two hundred and forty children, an average of 5.1 children each. As to the proportion of disease among the offspring, no calculation can be made in the absence of a definite statement of the number of the offspring. Suffice it to say, that only thirty-seven cases of abnormality are recorded among all these children. They include eight cases of deaf-mutism, six being in children of deaf mutes. This point will be again referred to. Eighty-eight of the one hundred and ten fertile marriages have no cases of disease among any of the offspring.

[To be continued.]

— From a French State paper, lately brought to light, says the *Popular Science News*, it appears that in 1770 the following parliamentary decree was solemnly passed and duly registered under Louis XV: "Whosoever, by means of red or white paint, perfumes, essences, artificial teeth, false hair, cotton-wood, iron corsets, hoops, shoes with high heels, or false hips, shall seek to entice into the beams of marriage any male subject of his Majesty, shall be prosecuted for witchcraft, and declared incapable of matrimony."

<sup>12</sup> Baines has assumed the extreme average length of time that married women continue to produce in this country, as, the one hundred years. That standard would not have admitted any large number of my own cases into the category of those having completed their reproductive career than does the one I have preferred.

## CASE OF VAGINAL EXTIRPATION OF THE UTERUS FOR CANCER.

BY W. H. BAKER, M.D.

Mrs. R— was admitted to the Free Hospital for Women, Feb. 11th, 1885, and gave the following history. She was fifty-four years of age; married, but has never been pregnant. The menopause occurred at forty-five, and in three years after the cessation of the menses they reappeared, and she continued regular for five years, or, until one year ago. The length of such periods was from three to five days, and the process was unaccompanied by pain. For the past year there has been a continuous flow of blood, though small in amount.

In April, 1884, however, there was an alarming hemorrhage which left her very weak, and she entered the City Hospital, where she gained considerably in general strength, though the slight hemorrhage continued. At the time of her admission to the Free Hospital for Women she was saturating from four to five napkins a day with bright blood. There was no foul odor in this discharge, and her complaint was of this loss of blood, weakness, and pain in the back and legs.

Feb. 12th, 1885, under ether, the uterine canal was rapidly dilated and the uterine cavity curetted with Sim's sharp curette. From the indurated feel conveyed by the curette, cancer was feared and the scrapings submitted to Dr. W. F. Whitney: Microscopical examination proved such disease to be present beyond any doubt. She was entirely relieved by this operation, and for four weeks there was no return of any hemorrhage or pain. She was, however, told that both would return, and that her only hope was in the removal of the uterus. To this operation she readily gave her consent.

March 19th, she reported a slight return of the flow, and on examination such was found to be present. There was not the slightest evidence in the appearance of the cervix uteri of any disease. The depth of the uterine cavity was three and one-quarter inches and the organ shown to be retroverted. There was no evidence of the disease having extended beyond the uterus. The vagina was small and the perineum firm.

March 24th. Ether having been administered, total vaginal extirpation of the uterus was performed after Schroeder's method, Drs. Davenport, Elliot, and Clark assisting. Great difficulty was met from the small size of the vagina and the firmness of the perineum, and it was not until the latter had been incised in the median line down to the sphincter muscle that the operation could be completed. Another serious obstacle in its performance was the fact that the size of the uterus was much increased by the existence of two small fibroids. Two hours and a half were occupied in the removal of the uterus, the pulse of the patient remaining good throughout. There was comparatively little blood lost. A drainage tube of soft rubber was carried through the wound into the peritoneal cavity, the proximal end of which was left protruding from the vulva; the perineum was closed with silver sutures; and the vagina was packed with iodoform gauze. Dr. Elliot had the supervision of the case subsequently, and Dr. A. W. Clark the immediate care of her. From the records I gather the following facts: She reacted well from the operation. The highest point which the temperature reached was at

the end of the first day, when the thermometer recorded 101°. Pulse 130°. On and after the fifth day it was normal until the twelfth day, after which time it was sub-normal, 96½ and 97° being recorded.

During the first day there was a large amount of bloody serum discharged from the drainage tube, thoroughly soaking a sheet which was folded thick under her hips. She was given small doses of morphia subcutaneously from time to time to relieve the restlessness which the enforced quietness of body induced.

The diet consisted of milk and lime water at first, then beef tea and Mellin's food. The urine was drawn with the catheter. The drainage tube was removed on the fifth day, and the packing of iodoform gauze on the seventh day. She was turned on her side the eighth day. The perineal sutures were removed and the bowels moved on the tenth day, and she was sitting up on the sixteenth day.

Now, at the end of three weeks, the wound in the vault of the vagina has closed and the ligatures are still intact in two masses in the outer angles of the cicatrix. She will be discharged from the hospital in a few days.

Aug. 11, 1885. Some two months ago, the patient came to the Out-Patient Department of the hospital, when the ligatures were removed, and she has since continued to do well.

## RECENT PROGRESS IN OPHTHALMOLOGY.

BY O. F. WADSWORTH, M.D.

### THE PATHOGENY OF SYMPATHETIC OPHTHALMIA.

THE theory, at least as old as Mackenzie, that the way of transmission of sympathetic ophthalmia from one eye to the other is along the optic nerve and chiasma, which for a time was almost entirely abandoned, but has been revived of late years, has received a strong support from the results of experiments undertaken by Deutchmann.<sup>1</sup>

The opinions advanced by Mac Gillvary, Kniro, Leber, and Luellen on this subject in general accord, although somewhat differing in details, have been given in the *JOURNAL*, volume cxi., page 518, 549.

Deutchmann, basing his experiments on the belief expressed by Leber that only septic infection of the first eye will excite sympathetic inflammation of its fellow, began by injecting septic material into one eye in rabbits. The constant effect was the destruction of the injected eye by panophthalmitis without inflammation of the other. He sought therefore a material which would cause as intense inflammation without destroying the eye by autophagocytosis, and found it in the spores of *aspergillus fumigatus*. When a solution of these spores in a three-quarters per cent solution of salt was injected into the opticus behind one eye a papillitis in the eye began to be developed on the following day, and six to fourteen days after the infection papillitis also appeared in the second eye. The inflammation did not progress farther, however, and the sympathetic papillitis subsided after a few days, leaving the disc of normal appearance.

Anatomical examination at the height of the process, seventh to tenth day after injection, showed neuritis and perineuritis of both nerves and of the chiasma. There was cellular hyperplasia in the substance of the

nerves and in their inner sheath and proliferation of endothelium in the intervaginal space. The inflammatory process had extended from the point of injection forward to the eye and backward to the chiasma, thence forward along the other nerve to the papilla of the opposite eye, and the choroid around the papilla was more rich in nuclei than in the normal condition. The pia mater of the anterior portion of the basis cerebri was also infiltrated with lymph corpuscles. The spores did not appear to have germinated, but were found in small rounded masses resembling tubercle, encapsuled by pus corpuscles and spindle cells. (It may be stated here that subsequent examinations proved that germination of the spores did take place to an inconsiderable extent.) Similar injections into the vitreous provoked purulent infiltration of it without leading to panophthalmitis, and were followed after an interval of seven or eight days by sympathetic papillitis of the other eye, which, as after injection into the opticus, subsided in a short time. Here too, neuritis and perineuritis extending from one eye to the other were found.

Becker<sup>2</sup> denied the propagation of sympathetic ophthalmia through the optic nerves because he had found in such a case with choroiditis and retinitis of each eye, that the inflammatory changes in both optic nerves had disappeared before reaching the optic foramina and that the intracranial portions of the optici and the chiasma were unaffected. He regarded the condition as ascending neuritis. Deutchmann refers to this case but holds that it does not prove Becker's view. In inoculating tubercle in the brain of the rabbit he found as a rule that the most marked changes on the sheath of the opticus occurred close to the eye and that the whole central portion of the nerve was intact, and yet the germ exciting the inflammation must have passed along the nerve or its sheath. He considers it therefore possible that in sympathetic ophthalmia the exciting cause of the inflammation may sometimes pass along the opticus and induce changes, first at its bulbar end. In the experiments here described also the inflammatory alterations were most pronounced at the bulbar ends of the nerves, so that this must be regarded as in a certain sense the place of least resistance.

So far the results of experiments were unsatisfactory in that a typical sympathetic ophthalmia, that is, an implication of the uveal tract and vitreous have not been produced. Suspecting that too rapid encapsulation of the spores might be the cause of the cessation of the process, injections into the vitreous were now<sup>3</sup> repeatedly made, four times in the course of twenty-four days. In two cases the attempt failed, in a third it succeeded. Papillitis of the second eye appeared in about a week; in a fortnight there was slight opacity of the vitreous, and in four weeks, four days after the fourth injection, numerous small prominent yellow masses appeared over the whole lower portion of the choroid. These rapidly multiplied, and increasing vitreous infiltration obscured the fundus. Left further progress of the affection might interfere with microscopic examination the rabbit was killed.

The injected eye presented advanced suppuration of iris, choroid, retina, and vitreous. The choroidal infiltration was in direct connection with that of the inner sheath of the nerve. Following the nerve backward there was found interstitial neuritis and perineuritis and dilatation of lymph vessels all the way to the chiasma.

<sup>1</sup>Arch. f. Ophthalmologie, xxviii, 3.

<sup>2</sup>Archiv. für Ophthalmologie, xli., 1.  
<sup>3</sup>Archiv. für Ophthalmologie, xxxv., 1.

The chiasma itself was moderately, its pial covering strongly, infiltrated with cells. The second nerve showed like alterations, of moderate amount near the chiasma, but increasing in intensity forward, and most pronounced close to the globe. The papilla of the sympathizing eye was greatly inflamed and swollen; the retina infiltrated with cells. The adjacent choroid was much thickened and consisted almost wholly of masses of pus corpuscles. The choroidal changes extended backward in the form of a dense infiltration of round cells in the pial sheath of the nerve, forward in diminishing degrees to the ora serrata. The iris was accidentally lost, and not examined. The vitreous contained numerous pus cells and membranes. Nothing pathological was seen in the ciliary nerves.

Deutschmann calls attention to the fact that his experiments showed that the inflammatory appearances in the tissues connecting one eye with the other are only temporary, and soon subside when the second eye has become affected; that it would not therefore be difficult in a later stage to find these tissues free from inflammation. On the other hand the propagated disease spreads where it finds a suitable soil, that is, in the sympathetically affected eye.

The inflammation may spread in the pia at the base of the brain sufficiently to offer clinical symptoms, and Moore has reported cases of sympathetic ophthalmia with brain symptoms.

The possibility of renewing the subsiding sympathetic affection in animals by reinjection of the infecting material offers an analogy to the late infection and recurrence of inflammation in the second eye in sympathetic cases in man. Here it may be supposed that the infecting material in the first eye may become encapsuled and so inert, either before it has infected or just after infecting the other, and later by some chance be again set free to exercise its harmful influence. The greater rapidity of the spread of the choroidal affection compared with that of the papilla may explain the apparent earlier appearance of the sympathetic inflammation in the uveal tract.

In a third paper<sup>1</sup> Deutschmann continues the subject. He had already suggested that the inflammation excited in his experiments was the result of a chemical irritant, because there appeared to be no wandering of the spores of *aspergillus* and no other micro-organisms could be found. To decide this question two sorts of experiments were undertaken.

1. *Aspergillus* was cultivated so as to exclude the presence of any other fungus, and the injection of the spores into the vitreous was followed by a propagated inflammation precisely similar to that observed before.

2. Croton oil was injected into the vitreous and produced an inflammation spreading along the optic nerves to the other papilla, but the death of the animal took place before the uveal tract became involved. These experiments seemed to demonstrate the efficacy of a chemical stimulus.

Nevertheless, as chemical irritation can seldom be the cause of sympathetic ophthalmia to man, and Leber has shown that septic infection is at least probable in such cases, Deutschmann returned to a septic agent and injected pure cultivations of *staphylococcus pyogenes aureus* into the vitreous. The first rabbit thus treated presented symptoms of meningitis on the second day, and on the morning of the third day was found dead. The microscope revealed a purulent inflammation of

the injected eye which extended along the nerve and its sheath to the chiasma, diminishing in degree as it proceeded; then it passed forward along the other nerve and its sheaths, again increasing in intensity as it approached the eye, and involving the papilla. There was also purulent infiltration of the pia. In all these parts the *staphylococcus pyogenes aureus* was readily demonstrated.

Of five rabbits treated with a weak solution of the virus, in the effort to avoid meningitis, only one gave a negative result, showing no change in the second eye, even after several weeks, and in that one the bulb burst and emptied its infectious contents on the third day after injection. All the others had sympathetic inflammation of the other eye, beginning in the papilla at varying intervals of time after injection, from five to six days to two to three weeks, but all died before the inflammation had had time to reach the choroid and iris. The autopsy revealed no anatomical cause of death, in particular no meningitis, of which moreover the animals had presented no symptoms during life. The suspicion that there had been a general infection of the blood was confirmed by cultivation of the *staphylococcus* from the blood and its fatal effect when inoculated in other animals. The susceptibility of the rabbit to general infection has been shown also by the results of experiments in inoculating tubercle in the eye. In all these cases there was discovered with the microscope an infiltration of pus cells, and of micro-organisms identical with those injected, in both optic nerves and their sheaths, in the chiasma, and in the papilla and surrounding parts in the second eye. In all the pia mater of the base was either absolutely intact, or contained in the immediate neighborhood of the chiasma lymph cells so few in number that it could not be decided with certainty if the physiological limit was exceeded.

Experimental evidence that only the early death of the rabbits prevented the cocci from producing inflammation of the anterior parts of the uveal tract in the sympathizing eye was furnished by dividing the nerve near the foramen opticum, injecting deeply into its peripheral end a solution of the cocci and applying a ligature so that none of the fluid could flow out. This brought about first, papillitis, later, irido-choroiditis and infiltration of vitreous, but several days elapsed before the process had extended to the iris.

The usual absence of meningitis in these cases is explained by the supposition that the flow of lymph naturally is from the brain to the eye. This theory is supported by the result of an experiment in which a solution of India ink was injected into the optic nerve. Four days later the rabbit was killed and all the ink found between the place of injection and the globe, none having passed upward.

Having convinced himself that certain micro-organisms did pass from one eye to the other, Deutschmann now examined twelve eyes which had been enucleated for sympathetic ophthalmia. Owing to the method of preservation six of these eyes were not in a suitable condition for the detection of micro-organisms. Of the other six, in five microparasites were found. Perhaps quite as important is the fact that in all the twelve eyes there was evidence of purulent infiltration of the whole uveal tract, and of either recent or former papillitis, neuritis and perineuritis; the infiltration of the choroid appearing to be in direct connection with that of the inner sheath and intervascular space.

<sup>1</sup> Archiv, für Ophthalmologie, xvi., 3.

Four eyes enucleated either after the outbreak of, or to avoid sympathetic ophthalmia were all found to contain cocci. Cultivation proved these to be the *staphylococcus pyogenes albus*, a microbe having like characteristics to the *staphylococcus pyogenes aureus* employed in the experiments above described, and differing from the latter only in color. Injections of it into the vitreous of rabbits produced precisely similar results in all respects. It is of interest moreover that although the beginning of the inflammation, the original perforating wound, occurred from two to four years before enucleation the micro-organisms had preserved their full vitality.

The same *staphylococcus* was obtained also from a sympathetically inflamed eye. A man received a severe wound of the right eye and refused enucleation till the left began to be affected. A year after the injury, iridectomy and removal of lens from the left. Cultivation from the piece of iris removed furnished the *staphylococcus pyogenes albus*, and a bit placed in the anterior chamber of the eye of a rabbit excited purulent irido-cyclitis and the animal died after two days.

Still another case, even more conclusive, observed after the main article was printed, and given as an addendum,<sup>5</sup> may be cited here. A boy of fifteen; wounded in right cornea, iris, and lens. Enucleation only permitted when after five or six weeks in the left eye. The disc was very red, the retina surrounding it gray, the vessels dilated and tortuous, the vitreous clear, the iris normal in appearance and secretion, but numerous fine deposits on the lower half of the posterior surface of the cornea. The aqueous of this eye was removed by puncture with a broad needle and carefully collected in a sterilized pipette. It brought away with it the deposit on the back of the cornea, which the microscope showed to consist of micrococci, endothelial and a few lymph or pus cells, and a network of fibrin. A portion under cultivation produced the *staphylococcus albus*, again injected into the eye of the rabbit gave rise to the same irido-choroiditis as in former experiments. The enucleated eye contained the same micrococci.

Deut-schmann concludes from all these circumstances that it is probable that the so-called sympathetic ophthalmia of man is an inflammation propagated from one eye to the other along the optic nerves, and that the exciting cause of the inflammation is either micro-organisms, which in some way have obtained access to the first eye or perhaps rarely some chemical irritant. To the objection that a papillitis is not always first observed in the sympathising eye, it is answered that sympathetic disease generally is brought to our notice only after disturbance of vision occurs, that is, when irido-cyclitis and vitreous opacities are already present. A number of cases have been published, however, in which neuro-retinitis was early observed, and these demonstrate that no visual impairment need exist at such a time.

—The death of a child, aged  $3\frac{1}{2}$  years, from sun-stroke is reported to have occurred last week in Dumfriesshire.

—Mr. Erichsen is to become a candidate for the representation of the Universities of Edinburgh and St. Andrew's in Parliament.

## New Instruments.

### A SKELETON TUBE FOR USE AFTER TRACHEOTOMY.

BY EDWARD T. WILLIAMS, M.D.

THE accompanying cut shows an instrument lately made for me by Messrs. Codman & Shurtleff as a substitute for a tracheotomy tube.

It consists of two parallel blades or branches, bent to the curve of a medium-sized tracheotomy tube, for insertion into the trachea. These branches are grooved

on the inside like a tube, and convex on the outside. The upper rectangular portion lies flat upon the neck, and is secured by tapes in the same manner as an ordinary tube. The screw, which is worked by turning the male branch round with a broad sweep, separates or approximates the tracheal branches at will, so as to fit any size of trachea, whether of a child or adult. It works into a female

screw drilled into the opposite branch. It is evident that when the two branches are brought to the proper degree of approximation, and inserted into the trachea, all further revolution of the screw is prevented, and the parallelism of the blades maintained by the tracheal walls.

The advantages of this instrument over the ordinary tube are twofold: it gives more space, and serves equally well for all sizes of trachea.

It is needless to say to any one, who has stopped to reflect upon it, that a common tracheotomy tube is a wholly unscientific instrument. It takes up room unnecessarily, and prevents the entrance of air and the discharge of morbid matter. There is no occasion for a circular tube to dilate the trachea, since the trachea is naturally dilated by the tracheal wings. All that is wanted is to keep apart the edges of the slit in the tracheal wall. It was an old practice to excise a portion of the trachea, but this left behind a tendency to hernia, or protrusion of the soft parts. Others employed hooks or stitches to drag apart the edges of the slit. The latter operation by sutures secured with adhesive strips originated with the late Dr. Martin, and has been performed successfully in several cases. It is a convenient makeshift, and likely to prove extremely useful in cases of sudden emergency, but can hardly take rank as a finished surgical procedure. The stitches are liable to tear through, as I found in a case of my own recently, when a second one had to be inserted on one side to maintain a firm hold. At the same time Dr. Martin is entitled to great credit for so clearly pointing out in his paper before the American Medical Association the disadvantages of the ordinary tubes.

The principle of the instrument described above is not in all respects a novel one. Split tubes of various patterns have been made and used before; but I think I can claim that nothing approaching mine in simplicity of construction has thus far been suggested.

They can be ordered of Messrs. Codman & Shurtleff, 13 Tremont Street, Boston, who have the model which I designed; or, I should suppose, of any ingenious mechanic.

## Reports of Societies.

## PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

APRIL 11, 1885, the President, DR. A. D. SINCLAIR, in the chair.

DR. F. H. LOMBARD reported, by invitation,

A CASE OF LABOR IN A WOMAN WITH SPONDYLOLISTHETIC PELVIS.<sup>1</sup>

DR. W. H. BAKER reported a

CASE OF VAGINAL EXTIRPATION OF THE UTERUS FOR CANCER.<sup>2</sup>

DR. DAVENPORT said that the difficulty of operating in this case could hardly be estimated. The patient had never borne children and the vagina had, moreover, undergone senile atrophy: the fibroids, too, were a troublesome complication. Unless the uterus is absolutely too large for removal per vaginam, even though, as in this case, it is considerably above the normal size, he believed the vaginal method was to be preferred to abdominal section; the mortality by the latter method being from 70 to 75 per cent; by the vaginal method only 25 per cent.

He was confident that the field of this operation would enlarge as increased skill in operating lessened the mortality. Not only cases of carcinoma and sarcoma would be proper ones for total extirpation of the uterus, but cases of changes in the mucous membrane and glandular structure of the body, which though apparently benign as shown by the microscope, yet show a tendency to recur even after repeated and thorough attempts at their cure by less serious means have been made.

DR. J. W. ELLIOT said that many were doubtful about the advisability of a radical operation for cancer of the uterus, as the results so far had been discouraging. Hofmeier had lately added to our knowledge on this subject by collecting and classifying the cases operated on by Schröder during the last eight years. From his statistics it appears that cancer of the body of the uterus is much less liable to return than cancer of the cervix or of the vaginal portion. Schröder has had the best results from supra-vaginal amputation of the body by abdominal section. After this operation 80 per cent were found healthy after a lapse of two years. After total extirpation per vaginam 35 per cent only remained healthy for two years. This apparent advantage in favor of the abdominal operation may be due to the more complete removal of the Fallopian tubes. The mortality of the operation itself is higher than the vaginal extirpation.

It seemed to Dr. Elliot, considering the nature of the disease as it occurred in the fundus and the comparatively isolated anatomical relations of the body of the uterus, that these results of Schröder's were not so surprising as they appeared at first glance. Dr. Elliot thought that an indiscriminate use of the radical operation was to be condemned, but that in favorable cases, especially of cancer of the body, the radical operation should be urged with more vigor than ever.

The vaginal extirpation has been done several hundred times. The technique is already pretty well settled and the mortality is not high. One recent operator reports twelve successful cases and no deaths from the operation.

DR. BAKER said that in his experience uterine cancer was confined to the body alone in not over two per cent of his cases. He had never seen primary corporeal cancer in women who had borne children; on the other hand, he had seen only one case of cancer beginning in the infra-vaginal portion in which there was no evidence of laceration of the cervix. When the cancerous growth is confined to the cervix and lower portion of the body, Dr. Baker preferred the operation described by him in the *American Journal of Obstetrics* for April, 1882; but in corporeal cancer he would remove the uterus either by vaginal extirpation or by supra-vaginal amputation.

DR. REYNOLDS queried whether cancer of the uterus, occurring as it does chiefly in married women, after the middle period of life, was not due to the stimulation by coitus of an exhausted organ which had ceased to respond to the demands made upon it.

DR. CHADWICK had noticed that cancer of the uterus was especially common in prostitutes, and he thought that contusion of the cervix by coitus after the menopause might well be a cause of uterine cancer.

## VOMITING OF PREGNANCY.

DR. M. A. MORRIS, present by invitation, spoke of a case of obstinate vomiting in a woman pregnant for the third time: every known remedy was tried, with only temporary benefit, and the patient's condition became very serious. Dr. Reynolds saw the case in consultation when the pregnancy was about four months advanced, and advised the continued use of morphia and nutritive enemata. Large doses of morphia were given up to one and one-fourth grains, and some relief obtained. Thus the patient continued until the end of four and a half months, when the vomiting ceased.

DR. CHADWICK said he had advised the chewing of spruce gum in cases of moderate vomiting of pregnancy, and had found relief to follow in one half the cases: whether the benefit was a reflex phenomenon from the act of mastication or was attributable to increased flow of saliva into the stomach thus induced, he could not say. He thought nausea and vomiting were often attributable to the fact that the patient went too long without food. At all events, he had found that eating a late supper and perhaps taking food during the night and frequently during the day, were often successful in the treatment of nausea.

## CHICAGO MEDICAL SOCIETY.

STATED meeting June 1, 1885.

The President, C. T. PARKES, M. D., in the chair.

## HAV FEVER, ITS CAUSES AND CURE.

DR. E. FLETCHER INGALLS read a paper with the above title, in which he said this disease had been the subject of investigation since it was discovered by Bostick in 1819, but only recently has the profession arrived at satisfactory conclusion as to its etiology and treatment. The disease is met with commonly in southern England and the United States, rarely in

<sup>1</sup> See page 169.

<sup>2</sup> See page 175.

Europe, and never among the natives of Asia and Africa. It is an aristocratic affection, being found more commonly among the residents of villages and cities and the opulent, rather than farmers and the poor, notwithstanding the theory that it is caused by the pollen of grains. Hay fever usually makes its appearance about the middle of August, and lasts until the first frosts of autumn. During an attack the mucous membrane covering the turbinated bones is greatly swollen, usually congested, the congestion often extending to the palate, fauces, pharynx and conjunctivæ. Microscopic examinations of the secretions have revealed numerous vibrios which were formerly thought to be the cause of the affection, but, it is more probable that their presence is accidental, as they may usually be found in the nasal secretions at other times.

The pollen of plants acts as a cause, not *per se* but as an exciting cause, being irritant to an exhausted nervous system. This nervous exhaustion renders the nasal nerves peculiarly susceptible to irritant substances. The theory of the nervous origin of hay fever has been generally accepted by the profession, although it has been only recently established that the tract involved is limited in the majority of cases to the lower turbinated bones and the lower and back part of the septum. In a considerable number of cases the sensitive areas are even more limited, though in some cases the middle turbinated bones are involved. The sensitive areas are not uniform in different cases. After referring to the symptoms and diagnosis of the affection the treatment was discussed. Weak solutions of quinine had been applied to the diseased regions on the theory that this drug would destroy the minute organisms which were formerly supposed to be the cause of the affection. While this remedy had proven efficacious in some instances, it was found that weak solutions of soda or other non-irritating drugs had proved as efficacious. Many remedies have been vaunted as specifics in the treatment of this as in that of other intractable, self-limited diseases, and they have been found sadly wanting in curative properties. Internal remedies that are of value are tonics and antispasmodics, and local remedies which sometimes give relief in the onset of the disease, are weak solutions of quinine, carbolic acid, tincture of opium, powders of morphia, bismuth, iodoform, etc., but they are not curative. For the asthmatic symptoms we can use the remedies appropriate to spasmodic asthma. However, it is only recently that we have found a method of treatment which promises to cure nine cases out of ten, and a remedy which promises to relieve the distressing symptoms in a fully developed case of hay fever. The latter is cocaine. Its action is such that it promises to be very valuable in the palliative treatment of the disease. A case of idiosyncratic catarrh, which closely resembles hay fever, came under Dr. Ingals' observation recently.

A two per cent mixture of cocaine and starch was blown into the nose as soon as the paroxysms came on. It gave immediate relief and was repeated as the attacks occurred. About two weeks after, another attack supervened and the same treatment gave relief. Cocaine will doubtless prove to be a remedy of great palliative power in this affection. Successful treatment by the galvano-cantury, which was first thoroughly tried by Dr. Roe, had previous to last May, been applied by Drs. Roe, Allen and Sajous, to about thirty cases, about eighty per cent of which were reported cured. As the disease is caused by a peculiar

sensitiveness of the terminal branches of the sphenopalatine ganglion and nasal nerves which are distributed over the septum and turbinated bodies, the treatment to be effectual must remedy this hyperæsthetic condition. The means adopted for accomplishing this purpose consists in applications of glacial acetic acid, carbolic acid and other escharotics, and searing the membrane with the galvano-cantury. The chemical agents often fail, but the galvano-cantury properly used seldom fails. Successful treatment with the galvano-cantury requires from ten to twenty sittings, and should be completed before the attack comes on. The method used is to first examine the nasal cavity with a slender, flat probe by which the sensitive spots are located, and then the cold electrode is passed into the nares, and having reached the point to cauterize, the electricity is turned on whereby the wire is heated. It is applied for the fraction of a second to the diseased tissue, causing a small superficial burn. This operation is repeated at intervals until all sensitive spots have been relieved, care being taken not to burn too large a surface, else severe inflammatory action may ensue. When skillfully performed the operation causes little pain, and if cocaine is applied previously no pain will follow. If no anæsthetic is used the pain may be relieved by spraying the parts with Dobell's solution. In conclusion, nearly all cases may be cured by systematic, thorough, superficial cauterization with the galvano-cantury of the hyperæsthetic portion of the nasal mucous membrane, providing the treatment is carried out between the attacks. Care must be taken to cauterize every sensitive spot, and not too much at once. The operation may be made painless by cocaine, and this drug may give relief during the attacks. General treatment must not be neglected.

Dr. INGALS then exhibited the battery which he uses, which is a large battery of the ordinary pattern. He said it was necessary to have a good battery with a large amount of reserve force so it can be used without the necessity of frequently agitating the fluid. The fluid must be often renewed.

Dr. F. O. STROCKTON opened the discussion by saying, that while he complimented the author on his paper, he thought more prominence might have been given to the causal relation of hypertrophied turbinated tissue to hay fever. In all cases of hay fever he had met, he had found hypertrophic nasal catarrh. If we treat hay fever, why not also treat the hypertrophic catarrh, which is a causal factor in the disease? He always removes the hypertrophied tissue on this account. In all other points he agreed with the writer, especially in the use of cocaine. Since this drug came into use, he has used it in several cases which resembled hay fever with good results. It gave more relief than quinine, belladonna, or any other drug.

Dr. ROBERT THURLEY protested against the use of the term hay fever, when it is shown it does not depend on the pollen of hay exclusively as a cause. He thought a better term to be idiosyncratic coryza, as it is caused by a multiplicity of circumstances. That morning he was visited by a patient in whom the symptoms were almost identical with hay fever, and if they had arisen at the proper season it would have been so diagnosed. He is a grocer, and the attacks occur whenever he has to handle coffee. Cocaine was used in a four per cent mixture with bismuth and it gave immediate relief. He has often in cases of

hay fever performed scarification of the inferior turbinated bones and mucous membrane of the septum with good results. He applies first a little cocaine, and very little bleeding follows. With reference to the locality of the sensitive areas in the nose, he thought that certain ineluctable pathological conditions of the mucous membrane gave rise to the sensitiveness which may be found in any region where the mucous membrane is in a pathological condition.

Dr. G. F. HAWLEY remarked that in passing the Eustachian catheter when it reached the posterior part of the turbinated body it often produced a reflex cough even in healthy persons. He had one patient in whom asthmatic symptoms occurred the moment this region was touched, and after the removal of hypertrophied tissue by the Jarvis snare, the asthma disappeared. Hay fever may be a neurosis or the result by reflex action of disease existing elsewhere. McKenzie, of Baltimore, relates a case of a young woman who had ovarian disease, and had attacks of hay fever during each menstrual period. On examination of the nose, there was found a small piece of hypertrophied tissue at the posterior extremity of the inferior turbinated bone, not large enough to obstruct the nares or give rise to any troublesome symptoms of itself, yet when it was removed the hay asthma disappeared forever. It would be hard to define the relation between this tumor and the diseased ovaries which caused monthly attacks of hay asthma, but it seemed to exist.

In conclusion, Dr. Ingals stated that he is of the opinion that a careful examination of every case of hay fever will disclose the presence of a sensitive area. In the case quoted in which the hay fever occurred during the menstrual periods, it was stated that there was a sensitive spot which when irritated, gave rise to the asthmatic symptoms. After cauterization the mucous membrane heals in about ten days. A small spot the size of a dime or nickel, should be cauterized and then allowed to heal perfectly, before another cauterization.

The society then adjourned.

### Recent Literature.

#### *The Curability and Treatment of Pulmonary Phthisis.*

By S. JACCARD. Translated and edited by Montagu Lubbock, M.D. New York: D. Appleton & Co. 1885. pp. 397.

The author's preface tells us that "this book contains the substance of lectures delivered in December, 1880, and January, 1881," that is to say, before the discovery of the bacillus tuberculosis; the organism was, however, in the air in more senses than one, although it had not yet been seen by the eye of man, and phthisis was believed to be an infectious disease before it was known precisely wherein the infection lay. What future study may bring forth, and whether some means may be discovered by which the bacillus nesting in the warm and seculent structures of the living lung, can be destroyed without simultaneous destruction of the pulmonary tissue, we do not yet know. Probably for some time to come Koch's great discovery must continue to illuminate pathology more than therapeutics; consequently, while we sympathize fully with the annoyance which the distinguished French professor must feel at the—in a certain sense—premature delivery of his literary offspring, we recognize the fact

that there is no reason for any feeling stronger than that of annoyance. The child is interesting, vigorous and fair to look upon, and the clothing provided by D. Appleton & Co., the American sponsors, is in every way worthy of their god-child and of themselves. We could wish that the English sponsor, the translator, had performed his duties better and left fewer traces of the French idiom behind him.

M. Jaccard holds the view that phthisis is curable, or he would hardly have written so large a book upon its treatment. To quote his own words, "pulmonary phthisis is curable in all its stages; this is the prolific notion which presides over the whole history of the disease, and which should unceasingly inspire and direct all medical action." The conditions of curability are discussed in chapters second and third, and among these there is one on which we must take issue with the author, who says "when it is asserted that pulmonary phthisis is curable, this proposition applies only to cases in which the disease receives appropriate treatment;" and again "nothing is so complex, so difficult to reconcile with the ordinary habits of life, so costly in expense as the treatment of pulmonary phthisis." We are far from asserting that the prognosis is not greatly influenced by the pecuniary circumstances of the patient; but on the other hand, we are convinced that relative poverty does admit of recovery, even when no change of climate is possible, and any treatment is necessarily very imperfect. That phthisis is sometimes self-limited has been clearly shown by Flint, and the frequency with which cicatrized apices are found, post-mortem, has been often remarked upon. That acute miliary tuberculosis is not absolutely hopeless as regards recovery is believed by M. Jaccard; he reports one case which has come under his own observation and alludes to those of Liebert, McCall, Anderson and Sick.

The "appropriate" treatment of M. Jaccard is indeed "complex," and the cases in which it can be carried out completely are comparatively rare. It is however well worth study, and will be found suggestive in detail, even if applicable in its entirety to but very few cases. It is impossible here to give a scheme of the treatment, which, of course, varies with the phase and stage of the disease, and the individual who is the subject of it. There are a few points, however, which we will briefly mention. To hydrotherapeutics and aerotherapeutics, especially as bearing on prophylaxis in those predisposed to phthisis, a fair share of space and attention are devoted. These methods of treatment are, in this country at least, in their infancy; but we have no question that they will in time grow to maturity and prove of great value in stimulating the general nutrition, and in improving the circulation in, and development of the lungs by more complete expansion of those organs in general but of the apices more particularly.

Cod liver oil is given by M. Jaccard in larger doses than is usual, four to six tablespoonfuls daily being the smallest quantity which he thinks capable of rendering any real service. Pyrexia is an absolute contra-indication to the use of this remedy, for which glycerine—Fissli daily—is to be substituted. It is important that the glycerine be absolutely pure, and a little essence of mint with a couple of teaspoonfuls of brandy or rum can be added to each dose if the patient finds the glycerine alone insipid. The subcutaneous use of cod liver oil is not alluded to. Against fever systematic

and energetic treatment is directed, an effort being always made to determine the special cause of the elevation of temperature. The fever due to ulceration is the most intractable to remedies; for fever which is symptomatic of a local process in the lungs, quinine is used, the hydrobromate being the form selected, and the drug being given hypodermically if the stomach is irritable. For the fever of absorption (hectic) salicylic acid and salicylate of soda are preferred, the former for administration by the stomach, the latter under the skin. We have ourselves strong doubts as to the possibility of clearly distinguishing these forms of fever clinically in many cases, and M. Jaccoud seems to admit that he is himself often enabled to do so rather from the effect of treatment than from the rational and physical signs. For failure to mention antipyrin and the other modern remedies of its class before they were discovered the author is of course not to blame. The salicyl compound he has found absolutely useless in those who use alcohol in excess.

The three concluding chapters, comprising more than an hundred pages, are devoted to the climatic treatment. The health resorts of Europe and Northern Africa are alone considered; but the value of the observations and opinions of the author is greatly enhanced by the fact that he speaks of all these health stations from personal knowledge.

In conclusion, it gives us pleasure to heartily commend the book as a whole, and to wish it a large sale. One cannot absolutely pin one's faith upon it, but if nothing was to be learned except from books quite above criticism the physician would economize much midnight oil, to say nothing of more precious things.

F. C. S.

*Manipulation of the Microscope.* By EDWARD BAUSCH. Illustrated, p. 96. Published by the Bausch & Lomb Optical Co., Rochester, N. Y.

The object of this book is best explained by the following statement of its author:—

"In order to accomplish the greatest good, I have started out in this little manual with the supposition that the purchaser or owner is a beginner, and absolutely ignorant of the microscope and everything which pertains to it, and therefore have attempted to convey, step by step, in as simple language as I could command, information which will lead to ease of manipulation, and give both pleasure and profit to those for whom it was especially written."

The chapters on the care of the microscope, and on testing objectives are especially clear and useful to the beginner, and to all who are desirous of obtaining correct information as to the elementary principles of microscopy, the book may safely be recommended.

*A Practical Treatise on the Diseases of the Ear, etc.* By D. B. St. John Rousa, M.D., LL.D., etc. Sixth Edition, Revised and Enlarged. Wm. Wood & Co. 1885. 8vo. pp. 718.

This book is too well known and appreciated to require any extended notice of this, the sixth edition. It is fully revised to date, and much enlarged; is characterized by the judicious and critical spirit and by the full appreciation of the labors of others for which the author has always been known. It, more than ever, deserves to retain the place it has so long held as a thorough reliable and entertaining hand-book of practice.

*The Ten Loves of Health: or how diseases are produced, and prevented, and Family Guide to protection against epidemic diseases, and other dangerous infections.* By J. R. BLACK, M.D. Philadelphia: J. B. Lippincott & Co. 1885. pp. 413.

This volume is a medical decalogue of Sanitary Science, or preventive medicine, in which the following subjects are treated at considerable length. Pure Air, Food and Drink, Exercise, Clothing, Sexual Function, Climate, Occupation, Personal Cleanliness, Rest and Sleep, Consanguineous Marriage.

The newer or supplementary portion of the work is devoted to the subject of infectious diseases, and has for its object "to enlighten and forearm the family and the public against the pestilential foes to their health and lives."

Many books have been published for the alleged purpose of reference in the family, the majority of which are either positively bad, or at least of doubtful value. This book is an exception, its precepts in the main being sound, and clearly stated. It is almost needless to add, that no book, however sound in its teaching, can safely be allowed to usurp the function of a trusted medical adviser.

*A Practical Treatise on Nasal Catarrh and Allied Diseases.* By BEVERLY ROBINSON, A.M., M.D., (Paris), Clinical Professor of Medicine at the Bellevue Hospital, Medical College, etc., New York. Second Edition, Revised and Enlarged. With 152 wood engravings. New York: Wm. Wood & Co. 1885.

Five chapters have been added to this second edition of Dr. Robinson's work. These are on:—(1) Aural Complications of Catarrhal Inflammation of the Nose. (2) Deflection of the Nasal Septum and Bony Obstructions of the Nasal Passages. (3) Ulcerous Coryza. (4) Adenoid Vegetations at the Vault of the Pharynx. (5) Mucous Nasal Polypi. The rest of the book remains practically as it appeared five years ago. The illustrations are numerous and well-executed. The type and material of the volume leave nothing to be desired, and in many ways the book will prove a valuable addition to the library of the general practitioner as well as to that of the specialist.

*A Guide to the Study of Ear Disease.* By P. McBRIDE, M.D., Fellow of the Royal College of Physicians, Edinburgh, etc. New York: J. H. Vail & Co. 1881. 8vo. pp. 198.

A Compendium of the anatomy, physiology, examination and diseases of the ear, unobjectionable and fairly complete, but like most of such compressed works more useful, in our opinion, to one already familiar with the subject and who wishes to refresh his memory on certain points, than to a beginner.

It deals chiefly with the more common forms of disease and entirely from a practical standpoint, omitting almost entirely descriptions of pathology, which have always seemed to us the most solid foundation for the student (or practitioner) to work upon.

It contains a number of chromo-lithographs of anatomy and of the appearances of the drum membrane in health and disease, which are well executed, and also a number of woodcuts of the more common instruments.

**Medical and Surgical Journal.**

THURSDAY, AUGUST 20, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

283 WASHINGTON STREET, BOSTON, MASS.

## THE STUDY OF DIETETICS.

THE address in therapeutics, by Dr. W. Roberts, at the last meeting of the British Medical Association was devoted to a phase of the subject of great importance, but which as the writer suggested, receives comparatively little attention in most of the schools of medical education. We refer to the subject of dietetics. Students are more or less fully instructed as to proximate principles, the differences between azotized and non-azotized foods, and the supposed function of each class. Yet after all, much if not most of the effect of food upon its economy, depends upon other considerations than the elements of which chemical analysis shows it to be composed. The form, the odor, the savor and the appearance of food are well known to affect favorably or unfavorably the digestive action and the nutritional value. Facility of digestion is not the great requisite in a nutriment, and he who should subsist entirely upon such articles as are shown experimentally to be converted into peptone with the greatest rapidity, would certainly lack much of being the best nourished of men. If this be true with persons in health it is reasonable to suppose that it may be so likewise with the sick. Who has not observed repeatedly that a patient may thrive better on some article which he craves, even though it be something abhorrent to the dietetic traditions of the profession, than upon the blandest slops so readily digested in the experimenter's laboratory? The fact is, that while digestion is a chemical process, the stomach is something quite different from a test-tube. There is often a mortifying contrariety in the advice given by different physicians to the same patient regarding some particular article of diet, one allowing and another forbidding it in a manner, which, as Dr. Roberts suggests, shows an utter want of any guiding principle upon which to base the decision.

Dr. Roberts assumes as an axiom upon which to base his conclusions, the statement that the concurrent customs of mankind in the matter of their food are the outcome of profound instincts and correspond to important wants of the human economy, being the fruit of accumulated and inherited experiences. Yet while

this is a correct assumption, it is true that special nations differentiate their dietary in a measure from that accepted by universal consensus, in accordance in part with the natural distribution of food-plants and animals and in part with the requirements of their climate and habitat. So too, the individual perhaps by a natural instinct modifies his diet to meet some requirement of his own economy. If the instinct of animals in a natural state is unerring as to what they shall eat, is it probable that human beings have a less perfect guide? It is just in proportion as this human instinct is overborne by the influences of restrictive legislation, of imitation, of fanaticism and of vicious habit, that dietetic errors creep in. On the other hand, as the commercial enterprise of a country brings a wider range of food within the reach of its people, physical and intellectual eminence are produced through the increased facility offered each citizen of obtaining just those nutriments best suited to his needs.

Of the many interesting and practical points of Dr. Roberts' paper, we have space to notice but a few. The subject of tea dyspepsia is elucidated in a measure by the observations of the author upon the intense inhibitory effect produced by tea upon salivary digestion. He says:—

"You can no more have tea without tannin than you can have wine without alcohol; and I found, experimentally, that tea infused for two minutes had almost exactly the same inhibitory effect on digestion as tea infused for twenty or thirty minutes. If you wish to mitigate the effects of tea on salivary digestion, you should direct the patient not to sip the beverage with the meal, but to eat first and drink afterwards. In this way time is given for the saliva to perform its functions unhindered. Another device is to introduce a pinch of carbonate of soda into the tea-pot; this removes the deterrent effect of tea on salivary digestion; it is a practice occasionally followed in some households, under the idea that soda helps to extract the virtues of the tea-leaves. It was found that the addition of so small a proportion as one per cent of the weight of the dry tea greatly mitigated its injurious effect on starch digestion, and that twice this quantity (two per cent) almost entirely removed it. This latter proportion corresponds roughly to ten grains of bicarbonate of soda to an ounce of tea-leaf."

Dr. Roberts recognizes, of course, that for certain forms of disease, a diet is requisite, having marked purposive modifications from the diet of the healthy. In considering the class of foods adapted to seriously sick patients, and hence deviating widely from the common customs of diet, he naturally gives a prominent place to milk. In speaking of the artificial pre-digestion of milk by the pancreatic ferments the practical difficulty is acknowledged that peptonization cannot be carried to any considerable extent without developing a bitter taste which is a great obstacle to the administration of the food, especially to children in whom such predigestion is sometimes so desirable. He claims, however, that in the cold the action of the ferment is

comparatively slow, and it takes some hours to produce an appreciable change of flavor. But as soon as milk, thus charged with the ferment, is swallowed and passes into the warm atmosphere of the stomach, it is rapidly digested. He has seen, in cases of typhoid fever, when undigested curds of milk were observed to be coming away with the stools, this plan followed by the immediate disappearance of these masses from the motions. But the palates of invalids are sometimes abnormally sensitive, and they detect, and resent the mere presence of the ordinary pancreatic preparations in articles of food, quite apart from the digestive changes produced by them. It is gratifying, therefore, to learn of a pancreatic preparation which is absolutely free from taste and smell. This preparation, made by a Mr. Bengier, is said to consist of the pancreatic enzymes in a highly purified state, under the form of a light, nearly white, powder. It is not hygroscopic, and may be kept unchanged for an indefinite period fully exposed to the air.

An important matter touched upon, is the difference in properties and effects of the flour made from the different cereals, and leguminous vegetables. Wheat, oat, barley, and pea flour are believed to have different effects, and a study of these separate substances is strongly urged upon the profession, in order that they may intelligently prescribe for each required case nutriment which are often carefully combined in the numerous prepared foods, but which in every secret preparation must always be given somewhat blindly as to the fitness for the special case in hand. The writer very wisely adds:—

“It is, I repeat, a serious disadvantage that the control of the preparation of food for the sick-room and nursery should pass from the hands of the medical attendant to those of the purveyor. In the matter of drug-giving, all enlightened practitioners are chary of prescribing secret remedies. Such a practice, it is felt, must be fatal to the intelligent use of drugs. So it is with providing food for the sick. What we want is to have at our disposal a supply of the several articles of food in their simple state, and suitable appliances in connection with the sick-room or nursery for cooking and combining them in various ways according to the exigencies of our patients.”

#### ON THE TREATMENT OF FURUNCLES.

GINGEOT has contributed to the *Bulletin Général de Thérapie* (t. viii), a valuable series of articles on the treatment of boils and carbuncles, of which the following is a summary. Brodie, in his *Lectures on Pathology*, published in 1846, advanced the view that the furuncle was a species of eruption analogous to small-pox, and a local expression of a poison circulating in the blood. Alphonse Guérin in the article *Anthrax* in “*Jaccoud's Dictionary*” (1865), teaches that furunculosis is a septicaemia, and assigns to it an intermediate position between the general affections which localize themselves, and those which, becoming generalized, result from a lesion primarily local.

The contagionness of furunculosis was established by Startin in 1866. He proved: 1, the auto-inoculation of the contagium by scratching; 2, the transmission from individual to individual by contact (as by occupation of the same bed); 3, the development of boils on the hands of surgeons and dressers consecutively to their being wounded with a bistoury which had been used in opening a furuncle. Lannelongue inoculated patients with matter from boils, producing at the point of puncture, furunculoid eruptions.<sup>1</sup>

It is not only proved that boils and carbuncles can be transmitted from man to man by contagion, but the active principle of the contagion, according to Gingeot, has been discovered. For this discovery we are indebted to Pasteur, who, on applying to the furunculoid affection the same means of study as had been applied by him to the investigation of the pathology of splenic fever, fowl cholera, and other virulent diseases, “has been able, thanks to the method of cultures, to demonstrate that every furuncle contains certain aerobic microscopic parasites, and that it is to these that are due the local inflammation and the pus formation.” This microbe is called by Pasteur the *torula pyogenica*; this mycologist, moreover, identifies this bacterium with that of abscesses of the soft parts, of osteomyelitis, and of puerperal fever; certain it is, however, that the product of cultures of furunculoid origin has never given rise, by inoculation in animals, to anything but simple abscesses, never to furuncles. Gingeot explains this fact by referring to the peculiarity of the tissue, (namely, the glandular apparatus of the skin, and especially the pilo-sebaceous glands) where the furuncle has its seat; the inoculation of the microbe would have a different result according as such inoculation were made into a follicle, or into the subcutaneous cellular tissue. M. Loewenberg has repeated Pasteur's cultures and inoculation experiments, and has confirmed them; he has also shown the part played by hairs in the collection of germs. According to M. Loewenberg, furunculosis is rather a local than a blood disease, the *torula pyogenica* being aerobic, and unable to wrest from the blood globules the oxygen it requires. The view which he adopts, and which Gingeot endorses, makes furunculosis a parasitic disease resembling scabies, and the old humoral notions respecting the etiology of boils and carbuncles are repudiated. It is, however, certain that furunculosis is attached by many bonds of union to the other virulent affections. A certain predisposition of constitution is necessary; the *torula* does not thrive unless it finds a favorable medium. This predisposition is found in certain debilitated states of the economy from overwork, alcoholism, diabetes, lithæmia, etc., in which there is such modification of the secretions of the skin as renders the piliferous and sebaceous glands a suitable habitat for the *torula pyogenica*.

The indications of treatment are: first, if possible, to cause the furuncles to abort; 2, this indication being

<sup>1</sup> On the Contagionness of the Furuncle. (*Courier Méd.* Nov. 27, 1866.)

impossible of fulfilment, to moderate the amount of suppuration; 3. to antagonize the constitutional condition which favors furunculous productions.

There are two principles laid down as the fruit of large experience: first, never to open early; second, seldom or never to open, even if suppuration have taken place, but to leave the boil or carbuncle to nature. Since the furuncle is a parasitic affection, the essence of the treatment ought to consist in the destruction of the parasite. One of the first precepts is to apply no poultices. Even when put on cold, the poultice has no power to stay the development of the furuncle, and when warm, it can only favor such development, as heat and moisture promote the vital activity of the lower organisms; moreover, the organic substances of which the poultice is made furnish a contingent of food to the parasite. Even when the boil has gone on to suppuration, the poultice is rather injurious than otherwise, aiding the penetration of new follicles by the microbe, by spreading the pus over the skin and keeping it in contact with the glandular orifices dilated by the heat.

One of the external remedies likely to be most successful in the abortive treatment of furuncle, and which Gingcot highly recommends, is the tincture of camphor. Both the alcohol and camphor in this preparation are excellent parasitocides. The camphorated spirit is applied to the part by means of a compress and allowed to remain in contact with the skin a few minutes. Thus treated, boils, if taken at the commencement, are frequently made to abort. The application should be made three or four times a day.

Another good agent for fulfilling the same indication is tincture of iodine, which should be painted freely several times a day over the furuncle and a little beyond. If applied till epidermic discoloration takes place, the iodine tincture does no harm, and if it does not always prevent, it certainly moderates suppuration, thus fulfilling the second indication and better than (perhaps) any other remedy. Gingcot believes that the iodine does good by its superlative parasiticide action: "the parasites cannot escape contact with the liquid which is introduced by capillarity into the glands, and by endosmosis into the acuminate vesicle of the top of the furuncle."

The same treatment is applicable in the early stage of carbuncle, and will often arrest its development; if, however, the progress of the carbuncle cannot be stayed, a strong solution of carbolic acid (equal parts of the strong acid and glycerine) must be brought in contact with the diseased tissue, as Dr. Eade of London recommends.

The central core or stem must be destroyed; this may be done by freely applying the carbolic acid through any openings which may exist in the centre of the swelling, or a sufficient opening may be made with acid nitrate of mercury.

When the furuncle is opened and discharging, the usefulness of tincture of iodine is ended. Then there is nothing better than borie acid applied in the form of fine powder, which is freely dusted over the boils, or

of the saturated aqueous or alcoholic solution which is kept constantly in contact with the diseased parts by means of compresses soaked in the liquid.

As for internal medication, Gingcot has nothing better to suggest than the recommendation to follow out the line of treatment several years ago indicated by Dr. Sidney Ringer, and endorsed by Dr. Duncan Bulkley at the last meeting of the American Medical Association. This consists "in the administration from the first of sulphide of calcium in small doses (one-sixth or one-fourth grain) every two hours." It is worthy of note that in the excellent paper which Dr. Bulkley read at this meeting, he coincides very nearly with the line of treatment above briefly summarized. He insists on the avoidance of poultices and other warm dressings; the avoidance of incision, "the entire process of opening and discharge of the pus and slough being left to nature;" the perfect protection of the inflamed parts from first to last by means of an ointment (preferably one containing ergot and zinc) thickly spread upon lint and changed as often as comfort and cleanliness require; the proper nutritive support of the system, (the surgeon should be chary of alcoholic stimulants); the necessity of suitable anodynes and tonics—as a tonic, the mixture of sulphate of iron, sulphate of magnesia, and sulphuric acid<sup>2</sup> is deemed especially beneficial; finally, on the persevering use of the sulphide of calcium pill in the doses above stated.

In closing the discussion, Dr. Bulkley said that he never opens a carbuncle, even when it is full of pus, as shown by fluctuation. He "leaves it to nature to supply a free outlet. He thinks that an incision leads to absorption of purulent material and blood poisoning."

#### — ♦ — MEDICAL NOTES.

—A cut in *Science et Nature* represents a practical application of antizymotic prophylaxis in vogue a century and a half ago. It shows a French physician, at the time of the pestilence of Marseilles (1720-21), equipped for his round of visits. He wears a complete armor of morocco, with high gloves and a helmet. The mask of the headpiece is extended forward into a sort of beak or bill placed in front of the nostrils. This artificial nose was stuffed with aromatics, and while it may have intercepted an occasional obtrusive bacillus, in appearance it suggests a Mardi Gras festival. To the caricaturist, the long flat duck-bill must have offered obvious suggestions, while to the patient, in the delirium of fever, the doctor may well have appeared like an apparition from the nether world. The rod which he carries in his hand seems to suggest that with all his antiseptic precautions the physician only dared touch his patient, as it were, with a tenet-pole.

—The Massachusetts State Board of Health recently sent out some fifty orders for drugs to various apothecaries in Boston and the neighboring cities and towns, for the purpose of seeking adulterations. Among the orders was one sent to an apothecary near Boston, for certain amounts of deodorized tincture of opium, white wine, syrup, precipitated sulphur, and zinc, all marked "U. S. P." The inspector brought back the drugs supplied in five different bottles as furnished by the apothecary. The opium was found to be just one-tenth its proper pharmacopoeial strength. The white wine was simply strong alcohol. The syrup was largely contaminated with dirt. The order for precipitated sulphur the druggist declared himself unable to fill, while for zinc, two salts of that metal are said to have been furnished for the purchaser to take his choice. A prosecution is looked for.

—Mrs. Clara T. Leonard of the Massachusetts Board of Health, Lunacy and Charity, has published an appeal to "respectable trustworthy persons in comfortable homes" to provide accommodations in their houses for receiving as boarders, homeless insane persons. The overcrowded condition of all the State Lunatic Asylums is well known, and of course if the right sort of persons could be brought together on an equitable pecuniary basis as hosts and guests, it would largely solve the problem now in the way of the accommodation of the increasing insane population. But the two great practical difficulties, first of determining with certainty just which of the cases are and will continue to be harmless, and secondly of protecting this class of patients, so many of whom would be aged and feeble, from the imposition and abuse at the hands of persons attracted by the chance of profit into taking this kind of boarders, does not seem likely to be easily surmounted.

—Dr. J. M. Fothergill, in one of his letters to the *Philadelphia Medical Times*, says: "New books are certainly coming out here, but in sparse quantity compared to the legion springing up on your side of the water, many of which find their way over here, and are in repute. Not only are the products of the United States in drugs and chemicals taking the lead of home productions, but in literature they are threatening the old supremacy of England, or, rather, the United Kingdom; for Edinburgh always has held a good position in medicine, and when a Dublin man girds up his loins for a book, it is usually for a good one."

—The daily papers announce that the Austrian government has established an office for the "practical testing" of all patent medicines. The expression seems to imply, that the investigation is of a physiological as well as a chemical nature. But it is doubtful, if even in Vienna, life is cheap enough to permit the material for such a test of all the nostrums. Perhaps, however, a paternal government, seeking to carry out the maxim, *fiat experimentum in corpori citi*, may take upon itself to apply the test in the person of the manufacturer. It is sometimes better than "sport to have the engineer hoist with his own petard."

## Miscellany.

### THE MODE OF CULTIVATION OF COCA.

DR. SQUIBB gives, in the *Ephemeris* for May, much interesting information regarding this drug.

The general method of cultivation seems to be common to Peru and Bolivia. The best coca is said to be produced on hillsides which are from 3,000 to 6,000 feet above the sea-level, and it is grown upon terraces of various widths on the sides of deep narrow valleys called "yungas." The seed is sown during August in beds, or boxes filled with earth, and by the following June, when the plants are eight or ten inches high, they are transplanted on the terraces about three feet apart, in a soil kept free from shade and from any other growths. By November the first lower leaves are of the deep olive-green color which marks maturity. A rich soil is needed, but fertilizers are not used, and, however good the soil, it is said to be rather rapidly exhausted by the plants, so that a succession of fresh plantings is kept up. The shrub grows to the height of from two to six feet, but the largest plants do not yield the best leaves. Each bush yields, as a rule, three crops a year, — or, in exceptional localities, four crops. The first is called the March crop, the gathering commencing in January. The second is the Saint John crop, beginning in May, and the third is All Saints, collected in October, and then the shrub is completely stripped of leaves. Moist seasons produce the most delicate leaves of finest quality, and droughts are very destructive to the crops, but as droughts in these mountains do not extend over very large districts, the total crop is not often seriously varied from this cause. The crops are gathered leaf by leaf, chiefly by Indian women and children, who stoop in front of each bush and collect only the leaves which are mature, in their aprons. The women are careful not to touch the top of the bush, for, if this be touched by man or animal "it withers and dries up." Men visit the women from time to time, and take the gathered leaves, in large sacks, to an enclosed yard, which is paved with smooth flat stones or slates, laid with very close joints and kept very clean. These pavements are so situated as to get the full force of the sunshine, and the first gathering of leaves is not brought to them until they are very hot from the sun's rays. The leaves are then spread thinly over the hot pavements, and being loosely raked and turned from time to time, are dry in from three to four hours in favorable weather. Sometimes, however, they have to be left over night, and are then liable to be damaged by dew. No gathering is done in very cloudy or damp weather, and damage only occurs from changes during the day after the collection has begun. When dry, the leaves are packed at once by means of a rude wooden press in square bales, of coarse cloth, of a cista, of about twenty-five pounds each. Two of such bales are put together under an envelope, generally made from the bark of the banana-tree, and such a package of about fifty pounds is called a tambor, or drum, and measures about 14 x 15 x 17 inches. When these parcels have to be sent across the coast range of mountains for exportation, three are put together in a tarpaulin covered package of one hundred and fifty pounds, and two of such packages make a load for a mule or other pack animal for this transportation of several hundred miles

through mountain passes. Coca is very easily damaged by the combined effect of heat and moisture, and is therefore always stored in cool, dry warehouses, and rarely handled or transported in damp weather or during the rainy season. This rainy season is from January to April, and therefore that stored on the west side of the coast range is alone available for export during the rainy season. When exported it is said that it usually starts in very good condition, and will reach its destination in the same condition, if carried in a cool, dry place. Such transportation is always stipulated for in bills of lading, but the proper precautions are generally neglected, and hence the worthless condition in which it is often seen. The only absolute security for it in transit is, therefore, to have it soldered up in tin or zinc, enclosed in wood, and such parcels generally contain two tambores, or about a Spanish quintal of a hundred pounds. United States Minister Gibbs, at Bolivia, who has made a full and interesting report to the Department of State on the cultivation of this drug, states the interesting fact that he is informed that habitual consumers of coca know nothing of toothache, and have their teeth in good condition to the greatest ages attained.

#### FERROCYANIC TEST PELLETS FOR ALBUMEN.

DR. PAVY, of London, has arranged a compact portable test for albumen based on the reaction long considered a delicate test for the presence of albumen, namely, ferrocyanide of potassium in the presence of an excess of acetic acid. It is figured and described in the *Lancet* for June 13th.

The whole appliance can be carried in the pocket like a pencil-case, which it only to a trifling extent exceeds in size. There is a celluloid tube for holding the pellets, and this fits into a glass tube, which is employed as the test-tube. No heat being required for the application of the test permits the glass tube to be made of sufficient thickness to be carried in the pocket without danger of breaking. The celluloid tube has a partition inside to keep the acid and ferrocyanide pellets separate, and at either end there is a screw top. The glass tube is provided with a metal cap which screws on and closes it. As the pellets are devoid of any foreign principle whatever, there is nothing to undergo deterioration by keeping. Citric acid is just as eligible for the purpose required as acetic acid. Enough is supplied in the pellet to secure the presence of free acid in any alkaline specimen of urine that is likely to be come across, provided the quantity mentioned in the instructions for the application of the test is taken. Should any doubt exist, two pellets can be used in place of one. The ferrocyanide pellet consists of the sodium instead of the potassium salt, on account of its yielding a looser and more speedily soluble product.

In using the test about a drachm of urine is taken as the quantity to be employed. An acid pellet is dropped into it, and with a little agitation is found to be quickly dissolved. One of the ferrocyanide pellets is next dropped in, and the urine again shaken to facilitate solution. If albumen is present, a precipitate immediately appears.

It is necessary that the test should be used in the manner which has been mentioned—that is, the acid pellet must be first dropped in and dissolved, and then

the ferrocyanide pellet added. The latter pellet it is which supplies the information required, and if a precipitate is by this pellet produced, the conclusion may be drawn that albumen is present, for the test does not precipitate peptones or other principles incidentally present in the urine. For sensitiveness the ferrocyanic will bear comparison with any other albumen test; and should no precipitate be rendered visible it may be safely inferred that no albumen is present. There is no need therefore for anything beyond the test itself being employed, and no spirit lamp being required, gives it a great advantage.

Sometimes a slight precipitate of uric acid is caused by the addition of the acid pellet, but it clears up under the addition of warm water and in no way interferes with the albumen test, which is made only by the ferrocyanic pellet in the presence of the excess of acid. Mucin also is precipitated by an acid, and the best plan here is to take two test-tubes and to treat the urine in one with the acid pellet alone, and in the other with both pellets. A comparison of the two will show whether albumen is present or not.

#### EXTENSIVE BRAIN LESION WITH SLIGHT SYMPTOMS.

DR. FOLLIOT related an instructive case at a recent meeting of the Medico-Chirurgical Society of Edinburgh (*Edinburgh Medical Journal*, June, 1885).

In January, 1884, a lady consulted him for pain in the left occipital region. A week after she fell into a deep sleep, out of which she awoke with all motor power abolished on the right side. She recovered, went to Moffat, enjoyed the summer, came home; and fell asleep for three days. After the administration of iodide of potassium, she remained well for some weeks. Six weeks before death she fell into a deep sleep. Two well-known neuropathologists were consulted. One of these gentlemen diagnosed a tumor of the base of the brain in the region of the sella turcica, the other a tumor of the pons variolii. The lady recovered, and three weeks before death had no symptom of any kind; but three days before her death fell into a sleep and passed away. A post-mortem examination showed the brain healthy in all respects, except that in the substance of the left lobe of the brain, anterior to the left lateral ventricle, there was a cavity which would contain a duck's eggful of thin sanious fluid. The whole arch of the brain covering this tumor, and to the right side of the left frontal convolution, was a gliomatous tumor, and a portion of the right frontal lobe also formed a tumor. There was nothing at all in the regions where tumor was diagnosed. The symptoms he believed to be caused by the variations in pressure of the fluid in the cavity. There was nothing in the history except that ten years before she had an epileptic fit on the death of a niece. He mentioned the case to show how necessary a post-mortem examination was for the purpose of verification.

#### LIMITS OF EXPERT TESTIMONY.

THE *Therapeutic Gazette* for April quotes a case from the New York Law Reports, as illustrating the proper limits of expert testimony. A child injured by a railway accident obtained a verdict on the ground of possible future consequences. The Court of Appeal,

holding that such testimony was improper, reversed the judgment, holding the opinion that "Consequences which are contingent, speculative, or merely possible, are not proper to be considered in ascertaining damages. It is not enough that the injuries received may develop into more serious conditions than those which are visible at the time of the injury, nor even that they are likely so to develop. To entitle a plaintiff to recover present damages for apprehended future consequences there must be such a degree of probability of their occurring as amounts to a reasonable certainty that they will result from the original injury." The testimony impugned was that of Dr. Spitzka, of New York, and was given in response to a hypothetical question. He said that the condition of the boy was very likely to be permanent; and in reply to the question what he meant by "very likely," he said: "I mean that the boy will always have some remnant of his injury, some reminder of it, great or small, that is certain. How much he will retain I cannot say; but I think he will very likely retain some." He added that the boy was very likely to retain the greater part of the symptoms, if he did not develop worse signs; and when asked what he meant by "worse signs," he said: "A patient sustaining such injuries, and presenting such premonitory signs, may develop traumatic insanity, or meningitis, or progressive dementia, or epilepsy with its results." This testimony was held by the court to be improper, as opening the door to all possible inferences on the part of the jury, and leading to probable extravagant estimates of harm; a new trial was, therefore, granted. The case is of interest, as showing the carefulness with which the evidence must be given by medical experts, when future consequences of an injury are under consideration.

#### THE PRICES AND PROFITS OF DISPENSING PHARMACISTS.

Dr. Squibb, in the *Ephemeris* for July, argues in favor of the equity of the current rates of profit of the apothecary, in opposition to the popular complaint against their high charges. He begins with the following hypothetical case:—

"A moderate dispensing store may be estimated at a rental of \$300.00 to \$400.00 a year, say \$1.00 a day. The furniture and stock of such a store would cost, say \$1,000.00. Interest on cost of this at 5 per cent, say sixty cents per day. Lights, fuel, water, insurance and taxes, say seventy cents per day. Wear and tear, breakage and repairs needed to keep the furniture and fixtures up to their value, say thirty cents per day. The sum of these estimated expenses is \$2.60 per day. A competent assistant, who is a graduate of pharmacy, should not receive less than \$2.00 a day, and an apprentice and errand boy fifty cents a day, making a total daily expense of \$5.10. If the sales from such a pharmacy be, say \$20.00 a day, the purchases needed to keep up the stock could hardly be less than \$10.00 a day. Then if the purchases be \$10.00 and the sales \$20.00, the gross profit is one hundred per cent. But the expense of selling for \$20.00 what cost \$10.00, is \$5.10 or 51 per cent, leaving a net profit of 49 per cent, or \$4.90 a day, which is less than 25 per cent of the sales, although it be 49

per cent on the supposed purchases. This \$4.90 a day or \$1,800.00 a year, is the total product of a man whose position is a very responsible and important one to the public around him, and to the physicians for whom he dispenses. His average history is, or should be, that he has served an apprenticeship of not less than four years, at an income of from 50 cents to \$2.00 a day. Has had an education, both primary and professional, which is rather expensive in proportion to his capacity to earn, and has graduated from some school of pharmacy. Has next served as assistant for two or more years, or for as many years as was needed to gain a reputation and an expert skill at his calling, which has enabled him to obtain the position of a proprietor. By this time he has a wife and children to support, and the social expenditures of his station in life. Under these circumstances it must be admitted that he is not overpaid, nor fairly chargeable with extortion in prices, even when he makes 49 per cent on his purchases.

"But this 49 per cent is only an average profit. Upon a prescription, the materials of which are almost without prime cost,—often only two or three inexpensive ingredients, with a large proportion of water or other cheap solvent or vehicle,—he is reasonably entitled to a far larger profit than the 49 per cent, because the value of all prescriptions, as well as all medicinal preparations sold, is not in the material, but almost entirely in the expert knowledge and skill with which they are prepared and dispensed. A pound of corrosive sublimate or an ounce of a strychnia salt, though not of high cost, if valued by their power to do good or harm, become of enormous importance to the community around them, and this value they get from the knowledge and skill with which they are dispensed."

Dr. Squibb draws however a sharp distinction between the responsibility and consequent claim to compensation on the one hand, of the man who prepares his own medicines and fills prescriptions, and those of the man who simply sells the wares, pills or otherwise of a large manufacturer.

The dispensing pharmacist, he says, is entitled to large profits just in proportion to the professional expert knowledge and skill exercised upon his calling. If he puts up a prescription he is justly entitled to a liberal reward for always being able and ready to do it,—night or day, Sunday or week day,—whether he has few or many to put up, for this is his legitimate work, and involves grave responsibilities. But when he sells somebody else's pills or disinfectants, he is only entitled to common mercantile profits, and this entirely irrespective of the smallness or largeness of his business, or of its heavy or light expenses, and such mercantile profits can never fairly exceed 15 or 20 per cent, even upon articles of infrequent demand.

##### MEDICAL STUDY IN GERMANY.—THE BONN SCHOOL.

ZURICH, July 21, 1885.

[Continued.]

MR. EDITOR.—Turning again to the Bonn Medical Clinic—it is on record that George Hackett once blew up and suspended animation in an old lady who called at his brother-in-law's office, during the doctor's absence, by

giving her first a powder of carbonate of soda and afterward one of tartaric acid, but I never before saw this procedure applied as a clinical device. Rühle, however, when he wishes to outline a stomach by percussion imitates George Hackett. It is very inconvenient for the patient but answers every clinical end.

Among many interesting autopsies in Bonn I saw one in a case of pelvic sarcoma in a man of advanced years. The left kidney was anemic, otherwise not remarkable, its fellow being decidedly hyperemic and containing an orange-red infarctus, of the size of an almond, of uric acid. This phenomenon being almost wholly confined to the kidneys of newly-born children, it excited considerable interest and suggested to Rühle the experience of Virchow, who two or three years ago nearly died of nephritis. He was vomiting and had other uræmic symptoms. Throughout his entire illness Virchow made careful and constant examination of his urine. One day when his friends despaired of his life he added acetic acid to his urine and was struck by the enormous quantity of uric acid which consequently formed. He immediately suspected the cause of his illness to be nephritis arthritica and at once began to drink large quantities of alkaline water. The result was a total disappearance of his ailment and his restoration to health. Virchow himself told the story before the Berlin Medical Society. I was curious to hear what explanation the Bonn pathologist would give of this unusual infarctus in the sarcoma case. At the next demonstrative course he gave the following theory: In the pyramids of the kidney is a system of lymphatics. These reabsorb the urine and a precipitate of uric acid followed. Under the microscope it was asserted that minute crystals of uric acid could be seen in the tubules of the pyramids. Another curious discovery in the Bonn autopsy room occurred in the case of a woman, previously supposed to be in sound health, who suddenly fell dead in the market place. Examination revealed a stomach distended with blood and a minute ventricular carcinoma which had ulcerated into a subcutaneous, small and heretofore unsuspected aneurism, death, of course, being due to a sudden hæmorrhage. The lungs were found to be in a condition of pronounced œdema and at the judicial investigation the question arose as to whether this might not have been a chief cause of death, but Koester, the pathologist, asserted that a secondary and very extensive œdema of the lungs might occur, and in this case undoubtedly did occur, within a period of two minutes. A third very instructive autopsy, and for the present I have done with this portion of my subject. During my stay in Bonn a man from Cologne, a brickmaker, died partially from chronic pneumonia, not much advanced, but whose death was hastened by the *enchelostomum duodenale*. This was the first autopsy in Germany upon a case of anchylostomiasis. The parasite was carried into Germany partly by the Italian laborers on the Gotthard tunnel, partly by brickmakers from an Eastern section of Belgium. It is supposed to find its way into the body in the form of larvae, which are taken either in muddy water or are carried into the mouth upon the soiled hands of the laborers in the tunnel, or of the brickmakers, the bricklayers never having the disease. By the use of filix mas Rühle had obtained sixty-nine of the creatures *in situ*. The post mortem discovered only fifteen more. They were found in the duodenum, each clinging by its teeth to a follicle of the mucous membrane, and rather difficult of removal. They suck the blood of their host like leeches, moving from one follicle to another, and leaving bleeding apertures behind them, so that blood appears in the feces. The disease is divided into an acute and chronic stage. It is acute when large numbers of the parasite are taken into the body at once, in which case the loss of blood may be alarming. In the chronic form there are fewer worms and the symptoms are less marked, but may become serious. After the worms begin their operations there is a steady, progressive anemia suggesting the progressive pernicious form. I have never before seen an autopsy which revealed organs and tissues so thoroughly emaciated of blood as in this case. One is led to doubt the possibility of such intense anemia

as the result of the ravages of the tiny bloodsuckers, and it is suggested that they may further interfere with and arrest nutrition. Nevertheless the combined and prolonged attack of scores and hundreds of these worms and the bleeding apertures which they leave as they change their location, finally and naturally cause an immense loss of blood. Microscopically the worm is white, perfectly round, and resembles the oxyuris vermiculosis; but the length of the anchylostomum is 6-10 millimetres in males, 10-18 in females, that of the oxyuris being 5 and 12 millimetres in males and females respectively. Its head is bent toward the back of the worm. Its home is in the duodenum, that of the oxyuris in the rectum. The latter may be removed by injections; to remove the former, requires strong doses of the filix mas. It likewise does not reproduce itself in the intestines. Under the microscope (a worm being gently pressed between cover-glasses and thus examined) it is seen to be armed with teeth about the mouth and that the eggs (0.05 mm. long, 0.023 wide) are oval, have granular contents which are fissiparous. In this condition the larvae are frequently found in the feces. Within the body of the worm red blood corpuscles can be distinctly seen. The prognosis is serious, for the reason that it is very difficult to expel the worm. The stools are to be strictly watched and patients not allowed to use a common water-closet. The parasite is found most frequently in Egypt, especially in the Orient and the tropics, and also in upper Italy. In cases of intense anemia, especially among miners and brickmakers, it would be well to seek for the anchylostomum.

*Insensation and Percussion* are taught four days in the week by Professor Finkler, whose thoroughness in detail and whose familiarity with physiology render the course extremely useful. As an instructor Finkler is unusually clear and scientific. In Rühle's absence he conducts the medical clinic. On one occasion he brought before the class a man, aged fifty-five, of robust appearance, who had been treated for diabetes mellitus. During the treatment Finkler had allowed him to eat anything he chose and to drink his habitual quantity of beer. Nevertheless the sugar entirely disappeared from the urine, no trace having been seen during the six weeks previous to his introduction to the clinic. The treatment had consisted simply and only of general massage performed twice daily, thirty to forty-five minutes on each occasion. Finkler's theory is that the sugar in the urine of diabetes mellitus is *muscle sugar*,—that as oxen for example, which have big muscles, use up more hydrocarbons (which go to the formation of muscle sugar) than albumen, so in a case of diabetes mellitus massage, or muscular action, will use up muscle sugar and retain albumen. By means of this treatment he has been successful in several cases. Children have responded less readily than have adults, but still the daily record shows a gradual and steady decrease in the amount both of sugar and of urine. Massage and other muscular exertion therefore are recommended in the Bonn clinic as remedies against this disease. Cases are related in which sugar was found in the urine before but not after exercise had been taken. The tubercle bacillus plays an important role in all cases of suspected phthisis, the diagnosis never being considered complete until the sputa have been examined for the vibrio.

Dr. Rumpf holds two clinics weekly for *nervous diseases*, and teaches the use of galvanic and electrotherapeutics. A pupil and former assistant of Erb, of Heidelberg, Rumpf is a very able man and is thorough in diagnostic detail, as are all the teachers of the Bonn school.

Finally, under the roof of the clinical department, is a very good course in laryngoscopy.

*Surgery* is taught by Professor Trendelenburg, formerly Langenbeck's chief of clinic. He devotes himself so earnestly to diagnosis that he considers it of more importance to students (and rightly) than operations, and in view of the fact that his material is very abundant and that his operations are not only skillfully done, but are performed with the help of the newest facilities, the value of his clinic can easily be appreciated. He takes unusual pains to make

students clear as to the diagnosis of a case and to give them every opportunity to profit by his teaching. Instead of keeping them at a distance during an operation, those who choose may stand around the operating table and watch every step and every smallest detail. To those who have taken an operative course, Trendelenburg gives facilities which exceed any I have before encountered. The student who is called upon to make the diagnosis is kept strictly to this part of the case until it has been completely exhausted by the method of exclusion. The student is then allowed to take the knife and open abscesses, enucleate small tumors, amputate limbs (excepting at shoulder and hip) and breasts, and in short to do any operation not especially dangerous or delicate in character. Trendelenburg, of course, meanwhile aiding the student in every needed way. Naturally this clinic is highly valued. The course in operative surgery on the cadaver, held four times weekly, is not deputed to younger teachers. Trendelenburg himself superintends the students during his days and Professor Doutrelepoint, who formerly made surgery his specialty, takes charge of the other two hours.

Before the introduction of Listerism a moderate lack of cleanliness did not appear to disturb the German surgeon. This has all been changed. Trendelenburg is a model of cleanliness, washing his hands a score of times during one clinic, and no student is allowed to examine a patient until after he has washed his hands in water and in a solution of corrosive sublimate. The locality requiring operation is scrubbed with soap and water and drenched with the sublimate solution which is colored by means of a little carmine and kept in closed gallon reservoirs of glass, suspended on the walls on either hand and from each of which proceeds a long rubber tube. The strength of the solution is 1-1000. Instruments, ligatures (always of catgut), and needles are kept in the ordinary solution of carbolic acid in dishes of glass. Sponges are kept and wrung out in the sublimate solution which is frequently changed. The dressings are first iodoformized gauze, next disinfected bags of moss, surgical cotton wool and finally disinfected bandages of gauze or gray flannel. Trendelenburg's operations are very successful.

The clinic for *syphilitic and skin diseases* is conducted by Professor Doutrelepoint, well known in connection with his studies upon the bacillus of *lupus vulgaris* (he read a paper upon the subject at the recent International Medical Congress at Copenhagen) and upon the bacillus of syphilis. His clinic is interesting and thorough and he has a plenty of material. One of the most striking of his skin cases during my visit was one of Keloid, which had arisen from a slight wound caused by a needle thrust under the thumbnail of the patient, a young woman. There were large and brilliant red cicatrices upon various parts of the body, especially between the mammae and ulcers upon the legs, all of which had followed a lymphangitis. Doutrelepoint considered that the needle may have conveyed some infectious material into the blood. He takes positive ground in regard to *lupus*, pronouncing this name a misnomer and ascertaining that *lupus* is not only tubercle of the skin but that it may be derived from an ordinary phthisis, and quoted the case of a woman who nursed her husband through tubercular consumption and afterward was attacked by *lupus*. Yet Kaposi, at Copenhagen, went so far as to say, in spite of twelve hundred cases of *lupus* which he had examined, that the disease is not tubercular, that it always appears first in childhood, and in maturity is always secondary. He has since recanted. Doutrelepoint also maintains that *lupus vulgaris* can no longer in any case be considered syphilitic because *lupus* is a tubercular disease. In regard to the present value of Lustgarten's syphilitic bacillus which Doutrelepoint claims to have discovered before Lustgarten published his observations, he says it seems to differ from the bacillus of tubercle in the dissimilar manner in which it absorbs color, but that to the eye, microscopically, there is no difference; that pure cultures has not yet been effective; that in syphilitic material only a few bacilli are found in relation to the number discovered in *lupus*; that in order to prove their character inoculation

must be attempted, and since animals do not have syphilis, this will have to be tried upon a sound man; that probably gelatine or blood-serum would be good culture fluids, but that enough has not yet been done to make the syphilitic bacillus worthy of acceptance without great reserve. Meanwhile he devotes a large portion of his time to careful examination of syphilitic material and has a large number of preparations. He uses the Lustgarten method of coloring and discoloration because it proves the most favorable. If at first other bacteria are found they disappear under the final procedures and leave the specific bacillus. These do not always appear at once. In preparations two months old Doutrelepoint was surprised to find bacilli which had not before been seen. Lustgarten claims that the bacilli are found in cells. Doutrelepoint has never found them in a cell and rarely, if ever, finds the bacillus in syphilitic tissue. He considers secretions, for example, from a condyloma, better than tissue, and finds the bacilli outside the cells.

In gonorrhea, Doutrelepoint injects a solution of corrosive sublimate, 1-20,000, until inflammation subsides, prefers it to any other medicament and also recommends the drinking of large quantities of water to dilute the urine. In syphilis he makes hypodermic injections of mercurial salts without injury to the patient, but on the contrary with excellent results. In the library of his department I noticed Dühring's text-book and atlas. The door of entrance to his classroom has large panels of ground glass which are used instead of the ordinary blackboard. In the surgical clinic are similar plates of glass set in wood and arranged to slide in a stationary frame. Colored chalks and charcoal are used, and the illustrations are much more conspicuous than upon the blackboard and are done with greater ease. Doutrelepoint is very clever, is genial with the students and a favorite teacher.

*Pathology* is taught by Professor Koester with the assistance of his colleague, Professor Ribbert. Of course every pathologist has his own views, and practitioners are much at their mercy. Koester is skeptical in regard to *all* text-books upon his specialty, but it must be said that he is a remarkably clear, painstaking and efficient instructor. An enthusiast in his line of work, he absolutely exhausts a topic before he abandons it, yet such is his ardor and such the zest with which he teaches that he holds the closest attention of the studious portion of his audience to the very end, and if students leave his room without a clear idea of Koester's views it is their fault, not his. Even the formality of the lecture hour does not check his contagious laugh, and by the post-mortem table he simply effervesces with wit and fun. But, nevertheless, in his practical course he is the strictest and most exacting of teachers, and on such occasions his never-failing laugh is probably at the expense of some blunder of the student. In making an autopsy he is one of the neatest, quickest and most clean operators I have ever seen. To study pathological anatomy under his guidance is a pleasure. So careful is he in teaching students how to make an autopsy that he rarely spends less than three hours upon one cadaver. Every step of the operation, every cut of the knife, its position, the manner of the cut and of removing the organs is taught with infinite care. Three students make a post-mortem, taking the head, chest, and abdominal cavity respectively, and each student is obliged to dictate the protocol. If an autopsy is to be made at the hospital for the insane, the names of the three students are posted on the board at the gate of the general hospital yard, and at the hour a carriage takes professor and the three students to the other hospital. Koester's demonstrative course occupies two hours twice weekly. Material is abundant. Microscopes are plentiful. Microscopical preparations exhibited to the class are made by Koester and Ribbert. The practical autopsy course is held on intervening days, twice and thrice weekly, in the new pathological institute, the demonstrative course still being confined to the old building, which is out of the grounds and very inconvenient. The new building is completed only in the portion devoted to post-mortem. When finished it will be perfect in its kind. Spa-

cious lecture rooms, a microscope room, laboratory, director's room, small apartments for special work, autopsy room, a spacious paved cellar, provided with wall-closets for cadavers and organs, the space between the closets being packed with ice. There are stone tanks and a vat for maceration and boiling. Elevators are to convey bodies to the various stories. Naturally there is abundance of water on all hands and a very convenient system of ventilation. Koester may well be proud of the building, which is arranged according to his own ideas of convenience.

He likewise teaches histology at the comfortable hour of seven A.M., at the Anatomical Institute. In this and the demonstrative course he is assisted by Professor Ribbert, an able and skilful instructor.

*Anatomy and physiology* are taught in the beautiful anatomical building. Its distance from the hospital makes little difference to the students, their first year being given to these branches, clinical instruction following later. It is necessary only to say that Nussbaum is Professor of anatomy, to make it evident that the students have every opportunity to become good anatomists. Material is never lacking. In every clinical course the students who are called to cases rarely escape searching questions which bring out their knowledge of anatomy and physiology. The physiological course is equally good, and is made very scientific by abundant apparatus of newest construction.

*Psychological diseases* may be studied under Professor Nasse at the hospital for the insane, and are illustrated by patients from the wards.

*Midwifery and gynecological* clinics are held daily in the women's hospital by Professor Veit, who is a better gynecologist than teacher. Indeed, he impresses one as feeling a stronger interest in his operation than in his students, who, however, fare better at the hands of Veit's very skil-

ful assistants. These not only teach practical midwifery, but likewise give operative instruction on the phantom after the Vienna manner. Veit has many patients, and the course is a valuable one if students look to the assistants for instruction. In regard to post-partum injections Veit gave this very literal reply to my question: "My theory is if a patient is doing well keep your hands out of her lap. I seldom use injections after the first day, unless warned by ill odors."

As a body the professors of the Bonn school are genial, gentlemanly men, easy of approach and free from all uncomfortable peculiarities. I am indebted to them for great courtesies.

That the Bonn school is very thorough and very desirable I trust I have sufficiently shown. The manner of teaching, namely, exhaustive treatment of every branch of study clearly indicates the character of the school.

After a student has given himself the benefit of such thoroughness he may benefit properly by the courses in Berlin and Vienna, but I believe not before.

In its situation, its surroundings, and in itself Bonn is very charming. It is quiet, orderly, and students may live at very moderate expense, and the University with its one thousand students, indeed the whole atmosphere of the place, induces to studiousness.

One thing I had nearly forgotten. In Bonn is the most exquisitely arranged and most classic museum of casts from the antique in all Europe. Here art students may receive perfect instruction from Professor Kékulé, and modelling and sculpture upon an anatomical basis are wonderfully well taught at his studio by Koppers, the sculptor, who is a cultivated anatomist. Professor Straub teaches in drawing and painting in a manner which has won for him a high reputation.

H. O.

## REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 8, 1885.

Deaths reported 1,755: under five years of age 452; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers and diarrheal diseases) 669, consumption 206, lung diseases 101, diarrheal diseases 529, diphtheria and cough 51, typhoid fever 16, malarial fever 17, whooping-cough 23, scarlet fever 15, measles nine, cerebro-spinal meningitis three, erysipelas two, puerperal fever one. From whooping-cough, New York 16, Brooklyn, Providence, and Lynn two each, Boston, Baltimore, Fall River, and Cambridge one each. From malarial fever, New York and Brooklyn seven each, Baltimore two, Nashville, one. From scarlet fever, Brooklyn six, Boston four, New York three, Charleston and Chelsea one each. From measles, New York three, Brooklyn

two, Boston, Baltimore, Providence, and Cambridge one each. From cerebro-spinal meningitis, New York two, Lawrence one. From erysipelas, Brooklyn and Baltimore one each. From puerperal fever, New Bedford one.

Cases reported in Boston: diphtheria 19, typhoid fever 16, scarlet fever 15, and measles five.

In 100 cities and towns of Massachusetts with an estimated population of 1,221,520 (estimated population of the State, 1,355,104), the total death-rate for the week was 23.27, against 23.38 and 23.83 for the two preceding weeks.

The meteorological record for the week ending August 8th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barom-eter.		Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### DEATHS.

Died in Worcester, Mass., August 9, 1885, George Anson Bates, M.D., M.M.S.S.

Died in Lowell, Mass., August 11, 1885, James Joseph Sullivan, M.D., M.M.S.S., aged twenty-eight years.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 8, 1885, TO AUGUST 14, 1885.

AZULI, THOMAS F., captain and assistant surgeon. Retired from active service August 10, 1885. S. O. 181, A. G. O., August 10, 1885.

CHAPIN, A. R., first lieutenant and assistant surgeon. Granted leave of absence for one month to take effect when services can be spared by the commanding general of the Department of Missouri, with permission to apply for one month's extension. S. O. 179, A. G. O., August 6, 1885.

WALKER, PHILIP G., first lieutenant and assistant surgeon. (Fort Conde d'Alene, Idaho.) Ordered for temporary duty at Boise Barracks, Idaho. S. O. 139, Department of Colorado, August 4, 1885.

#### APPOINTMENT.

KENDALL, WILLIAM P., to be assistant surgeon, United States Army, with the rank of first lieutenant, to date from August 12, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING AUGUST 15, 1885.

RYAN, H. G., passed assistant surgeon. To attend meeting of the American Association for Advancement of Sciences, at Ann Arbor, Michigan, and at conclusion of meeting to resume duty at the Smithsonian Institute.

BOYD, JOHN C., passed assistant surgeon. From navy yard, Washington, D.C., to special duty at Bureau of Medicine and Surgery, Washington, Navy Department.

LIPPINCOTT, J. C., passed assistant surgeon. To navy yard, Washington, D.C., as relief of Passed Assistant Surgeon Boyd.

OWENS, THOMAS, assistant surgeon. From special duty at Bureau of Medicine and Surgery, Navy Department, and waiting orders.

SAYRE, J. S., assistant surgeon. From U. S. R. S. "Independence," to Naval Hospital, Mare Island, Cal.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING AUGUST 15, 1885.

BAILLACHE, P. H., surgeon. To proceed to Delaware Breakwater Quarantine as inspector. August 15, 1885.

STOKER, GEORGE W., surgeon. Granted leave of absence for thirty days. August 10, 1885.

#### BOOKS AND PAMPHLETS RECEIVED.

## CONSAINGUINEOUS MARRIAGES: THEIR EFFECT UPON OFFSPRING.

BY CHARLES F. WITHERTON, M.D., OF BOSTON.

[Concluded.]

The first thirty-two cases are all from one isolated community on the north side of the island of Martha's Vineyard. They were kindly furnished me by Dr. L. H. Luce, a member of this Society, resident upon the island. The inhabitants are farmers and fishermen of average intelligence and good character, not addicted

to drunkenness. A lack of enterprise, associated doubtless with the nature of their occupations, seems to be the cause of their intermarrying. It will be noticed that all the instances of deaf-mutism occurring in the whole series of cases are to be found in this group representing one little town of Martha's Vineyard.

Cases 33 to 39 inclusive, are from another isolated community on Point Judith, in which was a marked inheritance of apoplexy and insanity. The remaining cases are scattered about, many of them in this vicinity. All are of American birth, and represent perhaps the better classes socially.

TABLE OF 108 CASES OF CONSAINGUINEOUS MARRIAGE.

Cases marked \* are of Consecutive Consanguinity.

No. of Case.	Relationship.	Husband's occupation, etc.	Years Married.	No. of children.	Healthy children.	Deaf Mutes.	Insane.	Idiots.	Blind.	Died in infancy.	Children's Children.	REMARKS.
1	1st cousin		25+	9	8							s dissolute; 1 nervous, bordering on insanity.
2	1st cousin		25+	8	3	5					(1st) deaf mute, had 2 sons, also d. m. (2d) had 1 son, healthy. 2 mar. relatives (see cases 3 and 4.) 3 unmar.	"All smart."
*3	1st cousin	son of No. 2	25+	2	1							Both above the average in intelligence, 1 died at 30, of phthisis.
*4	uncle and niece	son of No. 2	25+	2	2							Twins.
5	1st cousin		25+	3	2		1				See No. 6.	
*6	1st cousin	son of No. 5	25+	3								2 children below par in intelligence. One child a hermaphrodite.
7	1st cousin		25+	5	3			2			See No. 8.	The idiots also had talipes varus.
*8	1st cousin		25+	4	4							Wife = daughter of No. 7. Children "rather smart."
9	1st cousin		25+	1	1							
10	1st cousin		25+	5	1	1					(1st) 3 children, of whom 13 myopic, others healthy.	3 nervous (hysterical, neurasthenic).
11	1st cousin		25+	4	3						(2d) 3 child, died in infancy.	1 child died at 40 years, of phthisis.
12	1st cousin		25+	0							(1st) had several children, all healthy.	
13	1st cousin		25+	2	2							
14	1st cousin		25+	2	2						Daughter had 3 children, 1 d. of ovarian tumor.	
15	1st cousin		25+	6	3	3					(1st) deaf mute, had 4 child, also d. m., and 2 or 1 who were not; one of the former = No. 16. 5 others all had child, of average ability.	Wife = grandchild of 15, deaf mute.
*16	2d cousin		5	1				1			1 m. and had 2 deaf mutes.	
17	2d cousin		25+	4	1							
18	2d cousin		25+	3	2	1						The deaf mute also epileptic.
19	1st cousin		25+	1		1						
20	1st cousin		25+	4	4							
21	1st cousin		25+	2								(1st) d. of phthisis, aged 25. (2d) always an invalid.
22	1st cousin		25+	2	2						See No. 23.	
*23	1st cousin	son of No. 22	10	2	1							1 precocious, d. of cerebral meningitis.

Cases 1-32 inclusive, all farmers or fishermen.

TABLE OF 108 CASES OF CONSANGUINEOUS MARRIAGE. (Continued.)

No. of Case.	Relationship.	Husband's occupation, etc.	Years Married.	No. of Child b'n.	Healthy Child b'n.	Deaf Mutes.	Insane.	Idiot.	Blind.	Died in Inf. cy.	Children's Children.	REMARKS.
24	1st cousin		25+	3				1				2 had internal strabismus.
25	2d cousin		25+	2						1		1 still-born; 1 d. at 3 yrs. of scrofulous meningitis. Wife also had 1 miscarriage.
26	1st cousin		25+	7	5	2					One, of average intelligence and health, m. and had 6 chil.; 3 d. in infancy, 1 d. of epilepsy; 1 is an imbecile.	
27	1st cousin		25+	5	4							1 nervous.
28	3d cousin		25+	2	1			1				
29	1st cousin			1	1							1st wife.
30	1st cousin		25+	6	5	1						Second wife of above.
31	1st cousin		25+	2	2						Daughter had 8 chil.; some with scrofula. Two d. of phthisis.	
32	2d cousin		25+	3	3							One daughter d. of "softening of the brain" at the climacteric.
33	1st cousin			5	2		1				(1st) See case No. 34, (2d) mar., childless, (3d) two chil., 1 healthy, the other erratic and partially blind.	Wife's brother insane; one of her parents, two sisters and a brother d. of apoplexy. Husband d. of apoplexy. One child deaf (not congenital) and somnambulist. The daughter has periodical insanity, attributed to disappointment in love. A son d. at 40, of phthisis.
*34	2d cousin	son of No. 33		0								Apoplexy and insanity in husband's antecedents; himself healthy.
35	1st cousin		3	2			1	(st)			Children all unmarried.	Husband = brother of wife (in case No. 33). He d. of apoplexy at 60. Married cousin, mother's side. His sister (No. 33) married cousin, father's side.
36	1st cousin			2							(1st) see case No. 37. (2d) unmarried.	Wife = sister of wife, cases 33 and 38, and of husband cases 33 and 39. 1st child blind of one eye (congenital). 2d " " of both eyes " "
*37	2d cousin			2	1		1					Wife blind of one eye = daughter of case 36. Idiotic son d. at 17 years; girl, intelligent, d. young.
38	1st cousin			2	2						(1st) 3 healthy children. (2d) 4 " "	Wife = sister of husband of case No. 35. Died of apoplexy at 80.
39	1st cousin			1	1						Child unmarried.	Husband = brother of wife in case No. 38, and of husband case 35.
40	1st cousin	merchant	25+	6	6				1			Died of croup.
41	1st cousin	farmer	18	2	2							
42	1st c. 1 re.	carpenter	15	2	2							
43	1st cousin	fisherman	25	3	3							
44	2d cousin	merchant	3½	3	3							
45	1st cousin		15	3	3							
46	1st cousin	druggist	5	0								Wife had atresia vaginæ.
47	1st cousin	professor	25½	7	7					1	(1st) 4 children. (2d) 8 " " 1 son and 1 dau. d. in infancy. 1 son threatened with chorea, did not have it. (3d) 1 child, 1 dau. was temporarily insane (religious causes); recovered. (4th) 5 child. (5th) 6 child, 1 eccentric. (6th) 4 " " 1 slightly lacking mentally. 3d generation = 42 from 17 mrs., 11 fertile, 3 non-fertile all of one family. 4th generation. 4 from 1 marriage.	Husband a man of note, 1 dau., a little over-developed, nervous (vivacity and tendency to exaggeration). Original marriage about 1800. 1st generation, 7 children. 2d " " 31 " " 3d " " 42 " " 4th " " 1 " " Total in 1885 = 81 " All of these 81 persons healthy with the 2 exceptions noted and 1 grand-d. invalid from ovarian tumor. Family of unusual intellectual power. 1 Med. Mass. S. S.
48	2d cousin	professor	16	5	5							Deaf-mute in wife's family, and deafness not congenital in husband's family on the side where there is no relationship.
49	1st cousin			1	1						Married 5 years, no children.	

TABLE OF 108 CASES OF CONSANGUINEOUS MARRIAGE. (Continued.)

No. of Case.	Relationship.	Husband's occupation, etc.	Years Married.	No. of children.	Healthy children.	Dead Mates.	Insane.	Idiotic.	Blind.	Died in Infancy.	Children's Children.	REMARKS.
50	1st cousin			5	5							
51	1st cousin	physician	8	1	1							
52	2d cousin	apothecary	25+	3	3						1 married 3 years; has one healthy, remarkably bright child.	1 child d. acute disease.
53	1st cousin	agent	7	4	4							"All as active, intelligent and healthy as the best of American children."
54	1st cousin		17	3	3							"Very bright."
55	1st cousin	druggist	25+	4	4						1 married. 3 children, all healthy. 1 died of diphtheria.	
56	1st cousin	merchant	10	4	4							1 died of scarlet fever.
57	1st cousin			1	1							Wife d. of anemia soon after birth of child. Son now 21, "full, strong and healthy."
58	1st cousin	merchant	20?	3	3							Wife had 1 miscarriage.
59	1st cousin	farmer	25+	8	8						1st) 3 children. (2d) 3 " (3d) 4 " (4th) 4 " (5th) 2 "	Wife's brother died of "wasting palsy." Her family nervous; some of the daughters not very robust, but yet in good health.
60	2d cousin	merchant	11	3	3						Dau. m., no issue. Son m., " " In each of these cases there is uterine dis. in wife.	Son very bright, d. at 81, of an acute disease. Other son M.M.S.S.
61	1st cousin	merchant	25	5	5							All unusually intelligent. Son, athlete in college; now M.M.S.S.
62	1st cousin	farmer	25+	2	1					1		1st son very precocious, great memory, lawyer. 2d son died at 6 weeks, peculiar shaped head.
63	1st cousin	merchant		2	2							
64	1st cousin	farmer	1?	1	1					1		Wife = sister of wife in case No. 62. Child probably died of acute disease.
65	bro. & sist.			1						Unmarried.		Intelligent, but peculiar owing to facts of parentage becoming known in the village. Died of phthisis at 25-30.
66	bro. & sist.			1	1					Had 1 son, perfectly well in every way, now a leading citizen.		The son very strong, blacksmith, intelligent, carried on business for himself, lived to great age.
67	1st cousin	physician		2								Husband d. of phthisis. Both children intelligent and perfect, d. of phthisis at about 20 years.
68	1st cousin	farmer		1	1					Unmarried.		Wife 15 years older than husband.
69	1st cousin	merchant	25+	8	3						(1st) married, no issue. (2d) 2 children. (3d) 1 or 2 children. (4th) 1 child. All of 3d generation healthy.	2 and probably 3 of husband's brothers forgers, defaulters, etc. Seemed to have no motive for dishonesty. (Two of these brothers had only one child each; one of latter died in infancy.) 1 son well, served in war, died at 40 of phthisis. 2 sons are well except that they stutter, which has put them at disadvantage and interfered with their education. Neither can write a good business letter. 1 son an athlete in college, now not strong. 1 son in business but thought "rather wanting in smartness," died at about 35 of brain disease.
70	1st cousin	merchant	25+	3	2						1 married, no issue.	Husband's brother, chronic bronchitis and asthma many years, m., no issue. Another brother, invalid, unmarried. Wife, very deaf, has brother and sister each with issue. 1 son, well but not very enterprising. 1 daughter, deaf and nervous.
71	1st cousin	merchant	25	2	1							Mothers of husband and wife - sisters, belonged to a family, consisting of 4 daus. and 2 sons, all of whom d. of phthisis. Wife had 1 sister and 1 brother, and these have d. of phthisis. Dau. has narrow chest, subject to catarrh, colds and coughs, so that she "has to take care of" herself, but has had very little sickness, is very bright. Son, great eater, fat, dull and slow, super-numerary toe, myopia, tendency to pulmonary troubles.

TABLE OF 108 CASES OF CONSANGUINEOUS MARRIAGE. (Continued.)

No. of Case.	Relationship.	Husband's occupation, etc.	Years Married.	No. of Child b.	Healthy children.	Deaf Mutes.	Insane.	Idiots.	Blind.	Died in Infancy.	Children's Children.	REMARKS.
72	1st cousin	farmer	25+	8	8							1 dau. d. 1st pregnancy. All the children in this and foregoing case plain, though parents, especially wife (3) good looking. No relation between 71 and 72.
73	1st cousin	lawyer	25+	8	2				1	5	Daughter beautiful and accomplished, m. and had 1 imbecile child.	Hereditarily unknown. Idiot d. at 18. 1 son precocious, d. 7 years, cause unknown. Cause of infants' death unknown.
74	1st cousin	farmer	25	7	4					1		Infant d. umbilical hemorrhage. 2 others rather dull, one has some "malformation of throat."
75	1st cousin	professor		1	1							Husband and wife "of opposite temperaments."
76	1st cousin	manufactory	15	1	1							
77	1st cousin			7	2				5	2		The 2 healthy ones d. in infancy. 4 idiots died; one now living at 45, has a conical head.
78	1st cousin			1	1							Son now 20, very bright.
79	1st cousin			1	1							
80	1st cousin			2								Both "deformed;" son a fine bass singer.
81	1st c., 1 r.			7	4		3				All unmarried.	Husband's father drank and died insane. Wife's father had apoplexy late in life and died insane. Wife's brother now insane from use of alcohol. 3 children showed signs of insanity at puberty. 2 have passed puberty and are healthy. 2 are under 16 years.
82	1st cousin	merchant	18	7	5					2		Husband inclined to phthisis; also his father. Wife's mother nervous. 2 children d. cholera morbus. 1 d. scarlet fever; 1 stupid, slightly deaf. 1 dau. very nervous, has just m. double first cousin.
83	1st cousin	none	20	4	2							All child, bright. 1 has weak eyes, 1 has had "fits," epilepsy (?) but carries on business with success.
84	1st c., 1 r.	Member of the Boston Tea Party.	25+	11	11					1	In 1st gen. 11, "2d " 23, from 7 marriages (5 fertile). In 3d gen. 64 from 15 marriages (10 fertile, 2 infertile, 3 no record); 4th gen. 10 from 3 mar. (all fertile). Total descendants 98 in about 100 years.	Family of much intellectual power, including 3 physicians of note, all college professors. In the oldest branch 5 males 6 ft. 3 in. and upward. (2=6 ft. 4 in.) Only defects=1 dipsomania (2d generation) who got alcoholic tendency from mother (of another family), and perhaps 1 insane (2d gen.)
85	1st cousin			6	2					2	1 married twice, no issue.	Husband=grandson of 84. Wife=sister of dipsomania (see above). 1 dau. at 47 a dwarf and rather deficient in mind but not an imbecile. 1 son d. at 21 of phthisis.
86	1st cousin		25+									
87	1st cousin	farmer	25+	9	9					3	(1st had 11 children. (2d) " 2 " (3d) " 11 " (4th) " 3 " (5th) " 7 "	Husband an early Mass. settler, born 1694. Children died (except 3 in infancy) at 81, 61, 87, 78, and 47. (1 not known.)
88	1st cousin	farmer	25+	11	11					2	(1st) married a N. H. settler and was ancestress of well-known N. H. family. (2d) see case 89. (3d) " " 99. Records of descendants of others unknown.	Husband=nephew of 87 (born 1746), also brother of husband case 91. Wife=sister of wife case 91. Recorded ages of child, at death, 40, 61, 32, 62, 25, 65, 66.
89	1st cousin		25+	7	7						All m. and had issue.	Husband, officer, killed war 1812=son of 88. 4 children died at 75, 38, 60, 47, 72, 11 and 55 years.
90	1st cousin	U. S. Mars.	25+	8	8					2	3 married, not known if issue.	Husband=son of 88 and brother of 89. All children but 1 girls. All bright and pretty. Died at 28, 36, 32, 26, 15 and 19. No inherited disease.
91	1st cousin	physician	25+	9	9					1	8 married, all had issue. (1st) 4 children. (2d) 19 " (3d) 2 " (4th) 6 " (5th) 5 " (6th) 6 " (7th) 8 " (8th) 9 "	Husband=brother of husband in case 88, was medical director of Continental army in Revolution. Child d. at 67, 71, 58, 82, 78, 70, 80 (1 living at 75). The descendants of this family remarkable, comprising in 1st and 2d generations, 2 U. S. presidents, 1 bank president, 2 Atty. Generals (States), 2 overseers Harvard Univ., 3 state senators (1

TABLE OF 108 CASES OF CONSANGUINEOUS MARRIAGE. (Continued.)

No. of Case.	Relationship.	Husband's occupation, etc.	Years Married.	No. of Child'n.	Healthy Inf'n.	Deaf Mutes.	Insane.	Idiots.	Blind.	Dead in Inf. Vy.	Children's Children.	REMARKS.
*91	<i>continued</i>										No diseases in 2d generation except 2 cases of phthisis (d. 46 & 38) both in 1 family, 6 of the 50 child. of this 2d generation are recorded as having d. in infancy. 1 child in 3d generation has epilepsy.	pres. of senate), 1 college professor and president, 1 judge, 1 supt. of schools, 2 clergymen, 2 lawyers, 5 successful phys. (1 ex. pres. M.M.S.), etc.
92	1st cousin	naval officer	25+	6	5						1 m., has 1 healthy child.	1 child d. young (38y), cause unknown. 1 dau. invalid, neuralgia. 2 sons, healthy, dissipated. 1 son m'd d. scarlet fever.
93	2d cousin		15	3	1						1 Unmarried.	1 still-birth from neglected labor. 1 d. marasmus when a few hours old (born soon after a miscarriage). 1 dau. very intelligent and cultivated.
94	1st c., 1 r.		8	3		3					1st dau. m., childless. 2 next daus. married brothers, 1 without issue. 1 had 6 child. small in stature and some not robust. All very bright. Of these 1 m. and has issue.	Husband=brother of case 93. His mother had "weak lungs." The 2 older dau's were much worn by teaching before marriage, 1 of them (now aet. 50) said to have "weak lungs."
95	1st cousin	Cul. pioneer	1	1				1				Heredity not known. Child now 25 years, dwarf, cannot walk; brutish.
96	1st cousin	farmer	25+	3	1						1 m. (see case 97).	Husband's 2 brothers d. phthisis. 5 children of 3d brother d. phthisis. A sister had "weak lungs." 2 children d. phthisis at 24 or 25.
*97	1st cousin	merchant	25+	8	3					1	1 m., 2 healthy children.	Husband=son of 96. 1 child d. at 3, "serofula." 2 d. phthisis, aged 23 and 25. 2 others not robust.
98	1st cousin				3							Heredity unknown. 1st child, deaf, myopia, night blindness up to oph. examn., very bright. 2d not bright, talks indistinctly, 3d bright, feeble health.
99	1st cousin	none	25	2	2							Both d. acute non-tuberculous infantile diseases.
100	1st cousin	mas. paint'r	6	2	2					2		Both d. "quick consumption," at 21 & 22, bro. of husband case 105. Wife d. of phthisis =sister of wife case 103.
101	1st cousin	merchant	18	3	3							1 child d. phthisis. 1 drowned. 2 d. unknown causes. All bright, no diseases except 1 case phthisis.
102	1st cousin	merchant	10?	5	1						(1st) phthisis, m., childless. (2d) 7 healthy children.	Husband d. "quick consumption," at 21, bro. of husband case 105. Wife d. of phthisis =sister of wife case 103.
103	1st cousin	merchant	25+	16	16						1 son unm., 1 son m. (see case 105), 12 daus. all m., 1 had no child. The other 11 all had issue and most of them large families. All healthy. 1 dau.=case 108.	1 child d. phthisis. 1 drowned. 2 d. unknown causes. All bright, no diseases except 1 case phthisis.
*104	1st cousin		25+	6	6						(1st) son, m. (see case 105). (2d) dau., 4 chn., (3d) son m., has issue. (4th son, 3 chn., all healthy. (5th) unm.	Husband, son of case 103. 1 child, killed by accident, unmarried.
*105	1st cousin	merchant		3						3		Husband, son of case 104, grandson of case 103. The children all perfectly formed but d. just after birth.
*106	1st cousin		2	0								Wife=grand d. case 103. This her second marriage. By former husband had 3 chn.
*107	1st cousin	pay master United States Navy		1	4							Wife=grand d. case 103 and sister of wife case 106.
*108	1st cousin		25	10	9						7 chn. m., and all had issue (1 had 10 chn.), all healthy.	Wife d. of case 103. 1 child d. phthisis, unmarried.

Do these facts warrant us in supposing that there is a specific degenerative effect caused *ipso facto* by consanguinity? Regarding first the rate of fertility; the offspring averaged 5 to each marriage of relations, 5.5 to each case of the children of relations marrying kinsmen, and 5.1 where the children of relations married strangers. Unfortunately we have no fixed standard with which to compare these figures. The article on population in the Encyclopædia Britannica gives 4.51 children as the average product per marriage in

England. We know, however, that social and economic considerations affect the number of births as much as do physiological factors. I think it will be generally admitted that the average fertility of these cases compares very favorably with that of most American families. As to the general health rate of the children, we are again without a normal standard of comparison. Each must judge for himself as to the significance of the figures. For one, however, I doubt if more than three-quarters of the general com-

munity are free of the major and minor defects and diseases for which the children of these consanguineous unions have been excluded from the category of the healthy. The ratio of those dying of phthisis is remarkably small, being only 3.6 per cent of the whole number born. Even if we add those "not robust," the proportion of consumptives remains well within the average bounds.

There are three defects only which attract attention as being more frequent than would be expected. These are deaf-mutism, in 2.9 per cent of all the children, insanity in 1.7 per cent, and idiocy in 3.1 per cent. Regarding the first of these, we notice that all twelve of the cases of deaf-mutism in the children of persons related, and the eight cases which occur in the children of those consanguineously descended but not marrying kin, were found in one locality, viz., the town of Chilmark on the island of Martha's Vineyard. Of the eight cases last mentioned, six were the children of deaf mutes. Dr. Luce, to whom I am indebted for these facts, and who is well acquainted throughout the island, informs me that there has never been to his knowledge a case of deaf-mutism anywhere on the island save in the town of Chilmark. To be sure, he adds, that so far as he knows there is no intermarrying in the other portions of the island, because the inhabitants are more enterprising and have freer intercourse with the main land. He also sends me, however, the particulars of two families in Chilmark, in neither of which was there any consanguinity among the ancestors. The bride in one case was from New Brunswick and in the other was a Portuguese. The former gave birth to one deaf mute, the latter to two. Moreover, other degenerative conditions appear to prevail in this same town, owing to some cause which is not consanguinity. For I learn on the same authority of a case of idiocy where none of the ancestors had ever married a relative. Again, in another family equally free from any consanguineous "taint," among five children there were three hermaphrodites.

The seven cases of insanity occurred in four families. Four of the individuals so affected had a marked inheritance of insanity, three of them deriving it from both the father's and the mother's side. The two families in which the remainder of the cases were found, were both from Chilmark, and nothing definite is reported as to the mental soundness of their ancestry.

The proportion of cases of idiocy, while very small compared with the figures given in some of those observations that have become the standard for the popular ideas on this subject, is yet in excess of the ratio of idiots to the community at large. How far this proportion is representative of the actual facts, and how far it is affected by imperfections in the data, I am not certain. Of the thirteen cases of idiocy among the four hundred and thirteen children, six are reported from the two isolated communities already mentioned. One of these had a mother and grandmother both deaf mutes. The other seven cases all came to me through non-professional sources, and particulars regarding the parentage are unfortunately wanting. The memorandum as to one family said to contain five "fools" was given me through a second person, and it has not been possible to obtain any further information. I have included the case for what it may be worth, but do not feel quite certain that the total figures for idiocy are not unduly augmented by some error in the one case that furnishes so large a part of them.

Taking into account the fact already alluded to, that some of my lay informants have sent me an unfair proportion of the *causes célèbres* of their vicinity, the total results, it seems to me, are not such as to show any special or conspicuous deterioration peculiar to the children of relations. Of course no one will deny that a union, consanguineous or otherwise, which brings together two individuals having any disease or morbid tendency in common, will involve a direct danger to the offspring. Is it not possible, then, to account by the ordinary laws of morbid inheritance for such untoward results as sometimes follows the marriages of kindred?

The first objection that is raised against this view is that the children of relations are sometimes diseased when the parents themselves seem to be quite healthy. In answer to this, we may say that a more careful examination would often show that the opinion entertained by a merely casual observer regarding the parents' health was ill-founded. Again, the well-known phenomenon of atavism will account for cases where diseases are absent, or rather latent, in both the persons marrying, which were yet present in their common ancestor or in some close collateral branch, and which are capable of transmission through the married kinsfolk to appear again with reinforcement in their offspring.

Another and stronger objection urged by those who believe in a specific evil effect produced by non-renewal of the blood, is furnished by one or two diseases which are sometimes difficult to account for on the ground even of atavistic heredity. Foremost of them in importance for this argument, though a very rare affection, is hemeralopia or retinitis pigmentosa. Some of the leading of ophthalmologists believe that the disease has a specific relation to consanguineous descent. Dr. Derby, for instance, who has kept a careful record of all such cases, informs me that in a total of 12,130 cases in his ophthalmic practice, he has met twenty-three cases of retinitis pigmentosa. In nine instances, the individuals were descended from relations, in six the parents being first cousins, in three being second cousins, and in one the grand-parents being first cousins. In one instance there was no information obtained on this point, and in thirteen there was no relationship in any of the ancestors. In none of these twenty-three cases was any other form of weakness or disease noted. Dr. Derby has also kindly placed at my disposal his collection of the recorded cases of other observers. These amount, including his own just referred to, to two hundred and ten cases; in seventy there was relationship, in one hundred and thirty-nine no relationship, in one no information.<sup>20</sup> The records of the ophthalmic service of the Carney Hospital of this city, which have been kept with especial care on this point, and which Dr. Standish has

<sup>20</sup> The statistics reported by other observers are as follows:

Pagestecher reports eleven cases. Parents not related.  
Lechebier, ninety-five cases. Parents first cousins in forty-three.  
Mooren, thirty-four cases. Parents first cousins in nine; not related in the others.  
Hoover, two cases. No relationship.  
Stoer, one case. No relationship.  
Hoover, four cases. Parents first cousins in one.  
Hutchinson, one case. No relationship.  
Haase, one case. No relationship.  
Monoyer, five cases. No relationship.  
Jeffries, three cases. No relationship.  
Smith, three cases. No relationship.  
Widmer, one case. No relationship.  
Swanzy, one case. No relationship.  
Haidun, one case. No relationship.  
Lundell, one case. No relationship.  
Mooren, eight cases. Parents first cousins in three.  
Reichert, fifteen cases. Parents first cousins in five.

kindly gone over for me, shows in a total of 3,726 patients three cases of retinitis pigmentosa. In one there is no record as to consanguinity, in one there was no relationship, and in one the parents were first cousins.

Deaf-mutism is another defect that is often not transmitted directly from an identical form of disease in the ancestors, and it has therefore been ascribed to consanguinity of parents. But Rossa<sup>21</sup> states, that inasmuch as the disease is often due to inflammatory action, it is not likely to be transmitted as such by inheritance. He says that the causes of deaf-mutism are as numerous as those of deafness unaccompanied by mutism. The intra-uterine causes of the disease, operative perhaps in one-half the cases, are quite unknown. The proximate antecedents of hemeralopia are equally obscure. There is some reason to believe that transitory mental states, such as intoxication, may determine the procreation of an idiotic child. On the whole it seems likely, as has been pointed out by Dr. Child (*loc. cit.*), that all these diseases may stand in a relation, as yet unrecognized, to other neuroses present in the ancestors of the persons afflicted, as chorea is connected with rheumatism, or as the phenomenon of blue eyes in cats is associated with deafness.

If we were to accept the conclusions even of Chazeraim, who assigns 30 per cent of deaf mutes to consanguineous descent (a figure vastly in excess of anything that can be substantiated), and if we allow that a third of the cases of retinitis pigmentosa are in the offspring of relations; it yet remains true that a large majority of cases of these defects are due to causes independent of consanguinity. The hereditary taint under these circumstances is not always recognizable, but we know it is there. Why assume two specific causes to account for one effect, especially when the cause assumed for the minority of cases accounts for them no more intelligibly than would the other causes which is known to be operative in the majority of cases? Is it not more reasonable to suppose that those confessedly obscure nervous affections whose connection with any similar defects in the ancestors we are unable in some cases to trace, may yet, with growing knowledge of the pathogeny and relations of disease, be brought under those great laws whose effects upon heredity are so well established?

### A CASE OF GASTRIC ANEURISM.

E. PEABODY GERRY, M.D., JAMES A. PLAIN, BOSTON.

**HISTORY.** About eight A.M., July 31st, I was called to see Mr. J. The summons was urgent as he was suffering great pain. On arrival I found that the patient had been vomiting and was somewhat relieved; his bowels were constipated.

Soon after rising, at about seven o'clock, and without any warning, he felt a sudden sharp pain in what he called his spine, midway between his shoulder blades. This pain was excruciating, and extended into his left shoulder and from here diagonally across the chest to the right side of the body, where it located itself over the stomach and gall-duet; it was also felt in the right shoulder. It was paroxysmal, resembling

colic. As the patient had been troubled with dyspepsia for a number of years, and as the pain was in the back between the shoulder-blades, I thought it to be gastralgia of a rather severe type. There was one symptom noticed which indicated more than an ordinary attack of colic, namely, coldness of the hands and feet, and although I felt apprehensive on account of its marked character, I tried to flatter myself that severe pain in the stomach and especially the bowels is often accompanied by coldness of the extremities. Moreover the patient was quite bright and comfortable, and although looking ill, being an invalid, his face did not indicate the serious nature of his disease. He did not vomit I think during my first visit. I ordered sulphate of morphine, one-eighth of a grain, every hour, till relieved.

About eleven A.M., I was again summoned. The nausea, pain and vomiting had returned, and the patient looked much sicker than at my first visit.

There appeared to be a quartet of symptoms, namely, the pain which came first and was of a spasmodic character, followed quickly by nausea, vomiting and some faintness. This last symptom attracted attention, but not as much as it would, had not the patient been in delicate health for some time, and had the faintness been continuous instead of coming as a sequel to pain. The pain was in about the same place as at first, but seemed to be fixed more over the stomach and gall-duet; there was also some tenderness at this point but of small area. Larger doses of morphine had to be given. Was again summoned at two o'clock; and found the symptoms worse, the pain being more frequent as well as more severe, and followed as before by nausea, vomiting and faintness. The extent of tenderness had increased and although it was confined mostly to the right side over the stomach and gall-duet, yet when asked where he felt the pain, the patient always said it commenced in the left shoulder and that it ran from this point across the body into the stomach and gall-duet. An enema was ordered, but was not given on account of the extreme weakness that came on.

As nausea and vomiting were present, and as the patient had the appearance of kidney disease, I requested Dr. H. C. Ernst who had been called in consultation to examine the urine. He reported parenchymatous nephritis.

An attempt was made to feed the patient with milk and stimulate him with brandy, but he was unable to keep even this on his stomach. After four o'clock he grew worse rapidly, symptoms of collapse coming on. At ten o'clock P.M., Dr. Charles B. Porter was called in consultation. He was unable to make a positive diagnosis, but thought there were gall-stones impacted in the gall-duet and probable perforation of duet. He advised the continuance of the morphine, which had been given every hour or two according to pain. From this time till five o'clock the next morning when he died, he had successive sinking-spells.

The autopsy was made on August 1st, 1884, by Drs. Ernst and Whitecomb, ten hours after death. Body pale, somewhat emaciated. Rigor mortis marked. Head and thorax not opened.

Abdominal walls thin and the layer of fat less than usual. Section showed the intestines to be pushed forward by a large amount of blood, accumulated especially in the region behind the stomach and the spleen. The amount of blood was about three pints. It was fresh arterial and partly coagulated. The source of

<sup>21</sup> Practical Treatise on Diseases of the Ear, by D. B. St. John Brown, New York, 1885.

<sup>22</sup> Read before the Norfolk District Medical Society, March 21, 1885.

the hæmorrhage was found to be the rupture of an aneurismal sac of the gastric artery about one inch from the celiac axis. This sac was about two inches in diameter and occupied the lower half of the calibre of the vessel.

Perhaps it would be well in the light of the autopsy to repeat that the patient had been somewhat of an invalid for a year or two from dyspepsia and progressive debility, which the urinary examination showed to be due to kidney disease, and to say that the aneurism was probably due to lifting a heavy load. On inquiring as to the probable cause of the accident, I learned that about a month before his death, he had lifted the rear end of a loaded milk-wagon. On doing so he felt a sharp pain in his left side in the region where the injury took place; from that time to his death he had considerable pain at this point which he considered due to straining the muscles of the back. The injury to the artery evidently took place at that time, producing at last the disaster mentioned. The strain of lifting in so anæmic a person, injured the artery whose coats partook of the general debility.

**Diagnosis.** The point of greatest interest in this case was the difficulty in making a correct diagnosis, the disease not being fully determined until the autopsy. Here was a patient with severe pain in the region of the pyloric orifice of the stomach, describing his pain as being mostly on the right side, when singularly enough the injury was on the left side, with a history of chronic dyspepsia and symptoms looking toward kidney complications which the urine showed existed. After the first few hours, the idea of a simple colic had to be abandoned and we were obliged to look for more serious reasons for the severe symptoms which were rapidly growing worse, making it plain that the end was not far distant. From the location of the greatest pain, gall stones were thought to be the most probable cause of the trouble, although the fact remained that when the pain which was described as terrible was first felt, it was between the shoulder-blades, and at time during the day again located itself at this point. This acute pain did not indicate any-

thing positive, for it might have been a symptom of any severe lesion of the stomach or bowels. Its shifting character was the one thing that rendered the diagnosis uncertain. Perforation of the stomach at the pyloric orifice was also considered, although the character of the vomitus was not distinctive of any lesion of the mucus membrane, and the tenderness which at first was slight and afterward more general over the stomach and abdomen seemed to radiate from the gall-duct. Acute peritonitis from perforation was suspected from the cold extremities, the pain, nausea, vomiting and faintness, but that we should find a quart or two of clotted blood in the abdominal cavity was not in our calculation. Its location eliminated such diseases as ecchitis, circumscribed peritonitis from perforation of the appendix vermiformis, or any purely abdominal disease located below the umbilicus.

The autopsy explained the cause of the pain, and we judge that when the coat of the artery gave way, however small the opening at that time may have been, it was accompanied by the severe pain described between the shoulder-blades. We now know that each paroxysm of pain began at this point and not as we supposed lower down. The faintness was probably due to the very gradual loss of blood, although it always followed a paroxysm of pain, and until the last few hours he recovered from each attack and was quite bright till a return. Just why the region of the gall-duct was the most tender and painful spot it is somewhat difficult to say, now that we know that the seat of injury was on the left side of the stomach over its smaller curvature. The persistent vomiting in a patient known to have kidney disease suggested that perhaps it came from that cause, but a careful watch of the patient made it evident that the vomiting followed each severe attack of pain. Palpation did not assist us much, as the tenderness seemed to be about equally distributed over liver, gall-duct, and stomach.

During his sickness we supposed that it only remained to establish a differential diagnosis between acute diseases sometimes affecting the stomach and gall-duct. The occurrence of pain not excited by previous indiscretions in diet, or the taking of poisons or acids, the prominence of vomiting, the presence of tenderness, the persistence of pain notwithstanding the opium, the faintness, the weakened character of the pulse, the coldness of the extremities made one forget such diseases as acute gastritis and ordinary colic, and fixed the attention on acute peritonitis, the result of probable perforation of the biliary canal.

Finally I would call attention to the very unusual location of the aneurism, only seven such cases are referred to in the Index Catalogue of the Library of the Surgeon General's office.

— Mr. Henry Milne Edwards, who recently died in Paris, was the author of a number of works on subjects connected with natural science. He was a graduate in Medicine in 1823. His great work was in 12 volumes, and was entitled, *Leçons sur la Physiologie et l'Anatomie comparée de l'Homme et des Animaux*. He was for many years Dean of the Academy of Science and Member of the Academy of Medicine. He was also Commander of the Legion of Honor. His manual on Zoology was well-known as an English text book, and had been translated into most of the European languages.

A CASE OF PUERPERAL PULMONARY EMBOLISM.—RECOVERY.<sup>1</sup>

BY SAMUEL A. FISK, A.M., M.D., OF DENVER, COLORADO.

Mrs. F., a native of Maine, thirty-two years of age, was confined with her second child on the 31st of January, 1885. Her first labor was eight years previous, the child died when four months old, and since then she has not been pregnant until this time.

In the present labor the pains did not come on until eighteen hours after the membranes had ruptured and the water had come away, and even then they seemed to have been excited by the administration of quinine. Ten grains of chloral hydrate were given in the first stage with the evident effect of hastening the dilatation of the os. The presentation was occiput, position OLA, and the second stage rapid. Some difficulty was experienced in the expression of the secundines (by Credé's method) as the uterus contracted firmly on the membranes, close to their origin in the placenta, which lay in the vagina, and they were removed intact by introducing the hand into the vagina, getting back of the placenta and then using gentle traction over the index finger. Inspection showed that the rupture of the membranes occurred at the placental origin on the right. The child, a girl, died three hours after birth. She was cyanotic and although she cried lustily, the respirations did not seem to aerate the blood, and finally even artificial respiration and the interrupted current proved ineffectual to keep her alive.

Despite the excitement and sorrow attendant upon the loss of her babe the mother made a good recovery up to the twelfth day. With the appearance of the milk the bowels were moved with castor oil and an enema. The temperature only went as high as 100° F., and the pulse was 88 per minute. There was an abundance of milk, the breasts being distended clear into the axillæ. I had them rubbed with whiskey and bandaged, regulated the bowels with Hunyadi János water, kept the patient on liquid diet and gave quinine in two grain doses, three times a day.

I saw the patient on the evening of the tenth day, found the temperature and pulse normal, tongue clear, breasts soft, the milk not troubling her, and in every way she was feeling well and had been bolstered up in bed, and I was asked to present my bill.

That night, thinking that the Hunyadi that she had been taking had not acted sufficiently upon her bowels she took, on her own responsibility, four of "Carter's liver pills," which produced a tremendous straining and gripping sufficient to form hemorrhoids, but not sufficient to produce an operation. The following afternoon she took three "Brandreth's" pills and an enema of oil and water, had a fainting spell, a feeling of hardness around the rectum, cramping in the abdomen and straining. Finally at midnight she had one operation. At eleven o'clock of the twelfth day she was taken with what she called a heavy "chill." I was out of my office and did not reach her until an hour and a half afterwards, and had not seen her since the evening of the tenth day.

I found her pulse, which at normal beats seventy-six per minute, thin, shreddy, and beating 150 per minute. Respirations short, jerky, labored, and 50 per minute. She was cyanosed. The lips and face were purple,

there were great dark rims under the eyes, and the finger-nails were purple. She was bright and clear intellectually, complained of pain in the knees and arms and across her chest, and of her inability to get air into her lungs, but spoke especially of the frightful "chill" she had had, and of the pain, which was so intense as to make the very tips of her fingers tingle. I found that her chest was resonant throughout and that air reached every portion of her lungs. The nurse had stimulated her with whiskey when she had the "chill." Examination showed a bunch of protruding hemorrhoids which were somewhat painful.

On consultation with Dr. L. E. Lemen we decided to give six drops of the tincture of digitalis every three hours and watch the case. In four hours the pulse fell to 130 per minute and the respiration to 36. Temperature normal. The following day the pulse came down to 120 and the respirations to 28 and the cyanosis had nearly disappeared. The temperature was still normal and the skin warm and moist. Digitalis was given three times a day but she still complained of some pain across the chest.

On the evening of the fourteenth day after her confinement or the second after the "chill" her pulse was 108, respiration 24, and temperature normal.

Third day after the chill pulse 96, respiration 24, temperature normal. Coughing a little and raising a slight amount of rusty sputa. Examination showed a slight harshness of respiration under the left nipple, the spot where she complained of, there being some pain. There was also a slight amount of dullness over the same spot, but so slight as to be questionable.

She continued to improve, her pulse and respirations returned to the normal, the cough and expectoration ceased in a couple of days, her breathing became full and deep, without pain; when on the eighteenth day after her confinement she complained of pain in her left leg. On examination I found it tender to the touch, along the course of the femoral vein and especially so at the saphenous opening. This tenderness extended, together with a very slight induration, into the calf of the left leg. The treatment for this consisted in poulticing and absolute rest, and at the same time iron was combined with the quinine that she was taking. The bowels were left constipated for five days. The pulse rate remained at from 76-88. Respirations normal, and the even temperature was never over 99° F. In fact there was no constitutional disturbance.

In one month from the time of her labor she was up and walking a little, but to-day, now nearly six weeks, she is troubled with swelling of the left leg and foot, probably due to a weakened condition of the femoral or saphenous vein, which condition is relieved by bandaging with rubber.

This case is of interest because of the unusual number of complications it presents, but chiefly as being a case of plugging of some portion of the pulmonary circulation, in which a recovery has taken place. That this plugging was embolic seems probable for the following reasons. There has never been any evidence of heart lesion or of roughening of the valves. The circulation has always been strong and regular. The intense rigor and frightful dyspnea came on suddenly and were not a gradual development. With them the pulse took a bound from 76 beats per minute up to 150 per minute, and intense cyanosis supervened. All of these symptoms followed a straining at stools, which was sufficient to either produce hemorrhoids of large

<sup>1</sup> Read before the Denver Medical Association, Tuesday evening, March 16, 1885.

size, or else to bring down some that had existed unbeknown to the patient.

Further, the appearance of cough, with rusty sputa, taken in connection with the limited area of dulness and harshness of respiration found in the left chest make it probable that a small spot of embolic infarction existed there. The appearance of the *phlegmasia dolens* subsequent to the attack spoken of, may shed further light upon the case as showing that there was either a uterine phlebitis,—which was improbable, as there were no corresponding constitutional symptoms, or that there was an impediment to the venous circulation on the left side due probably to an extension of a uterine thrombus.

My theory of the case is as follows:—that in the tremendous gripping and straining at stool a uterine clot was dislodged, or partially dislodged, from some sinus and was left protruding into the course of the venous circulation. That, inasmuch as this was only on the twelfth day, and as has been shown by Playfair, softening of such thrombi is not apt to occur until the nineteenth day, it took about eleven hours for a portion of this thrombus to be separated from the main body, and then it was carried on, through the heart into some small branch of the pulmonary artery, causing a sudden upsetting of the normal equilibrium existing between the respiration and the pulmonary circulation. Subsequently to this, by an extension of the original thrombus the circulation in the left iliac vein was impeded and hence the production of *phlegmasia dolens* on that side.

That recovery ensued, I can only regard as due to the fact that, in all probability, only a small branch of the pulmonary artery was obstructed: but having witnessed the distress produced in this case, I can readily understand that an agonizing death must be the result when the main artery is occluded by either a thrombus or an embolus.

#### REPORT ON RECENT PROGRESS IN THORACIC DISEASES.

BY FIELD C. SHATTUCK, M.D.

##### "SPIRAL AND CENTRAL THREADS" IN SPUTUM AND THEIR SIGNIFICANCE.

IN 1872, Leyden in writing of asthma called particular attention to peculiar sharp pointed crystals found by him in the sputum of some cases of asthma and apparently identical in nature with crystals already described by Charcot and Robin as occurring in a leucæmic spleen and since then detected in other situations; it was at one time supposed that these crystals stood in some causal relation with asthma, provoking spasm by the irritation produced by their very sharp angles. At the same time Leyden spoke of spiral bodies apparently consisting of coagulated mucus also seen by him in a thoracic sputum, but this observation seems to have attracted little attention until Curschmann in 1883 brought these bodies more prominently into notice; they are now figured in the more recent German hand and text-books. The latter observer considered the presence of these bodies pathognomonic of an affection of the mucous membrane of the finest bronchial tubes attended by an exudation on the surface of the membrane; he called the affection "*bronchiolitis exudativa*;" thought it to be nearly always chronic, sometimes less ordinary, occasionally uncomplicated, but apt to be as-

sociated with other chronic changes in the larger bronchi or lungs, and clinically characterized by asthmatic attacks. These spiral threads have now been detected in the sputum of pneumonia by Vierordt, Jaksch, Vincenzo, and Pel,<sup>1</sup> as well as by Curschmann himself, and some controversy as to their nature and precise significance is now going on. Curschmann,<sup>2</sup> who up to the present writing, has the last word on the subject, still holds that the spiral threads with their peculiar central formation—which, by the way, does not represent a canal—indicate an entirely independent affection which must be sharply distinguished from simple fibrinous bronchitis, whether the latter be part of a pneumonic process, or uncomplicated by any changes in the alveoli. Pneumonia and acute exudative bronchiolitis may run their courses side by side and disappear together; pneumonia may befall a person the subject of chronic exudative bronchiolitis with spasmodic asthma; and lastly, the pneumonia complicating an acute bronchiolitis exudativa may recover, while the latter may develop into a chronic process and pave the way for asthmatic attacks by exciting bronchial spasm. In none of these cases of pneumonia were the Charcot-Leyden crystals seen in the spirals, a fact which leads Curschmann to think that they are found only when the exudation is retained a considerable time at its seat of formation, that is, in chronic cases. Fibrinous casts of the minute and smaller bronchi are found often enough in pneumonic sputum, but their appearance is certainly, and their composition probably quite different from that of the spirals under discussion. Curschmann denies that any intermediate forms are found. (The spiral formation is attributed to the rolling over and over to which the exudation is subjected while passing from its seat of origin outwards until expectorated: fibrinous casts of the bronchioles are subjected to the same conditions, and that they do not assume the same or similar forms is evidence that they differ in composition or some other important respect. Lewy<sup>3</sup> publishes a preliminary notice of his investigations, and promises an elaborate article later. He has found the spirals in cases of bronchitis, both acute and chronic, without the least asthmatic complication; and the crystals in acute bronchitis and phthisis. Further light is certainly desirable, and will doubtless be afforded.—*Rep.*)

##### ASTHMA PRODUCED BY A LINED POULTICE AND BY THE SMELL OF COOKED HARE.

Dr. Kingsbury<sup>4</sup> reports the case of a patient with an ulcer of the leg, for which he ordered a lined poultice. The patient objected, saying that for the last four years such an application had invariably been followed by an asthmatic attack, but the doctor insisted, and three hours later was summoned, finding his patient livid and gasping for breath. Dr. Neale, in commenting on this case in the *London Medical Record*, alludes to a case in which a lined poultice is stated to have caused urticaria, "a fact interesting in connection with Sir Andrew Clark's statement at the Clinical Society, January 9, that he believed spasmodic asthma to be a sort of urticaria of the bronchial mucous membrane."

Warner<sup>5</sup> reports a case of urticaria during the continuance of which several attacks of asthma and severe

<sup>1</sup> *Zeitschrift für Klin. Med.*, 1885, Bd. IX., p. 29.

<sup>2</sup> *Deutsch. Archiv. für Klin. Med.*, 1885, Bd. xxxv., p. 578.

<sup>3</sup> *Centralblatt für Klin. Med.*, 1885, p. 255.

<sup>4</sup> *British Medical Journal*, 1885, i., p. 278.

<sup>5</sup> *Ibid.*, 1885, i., p. 5.

vomiting occurred. On two occasions the eruption was noticed on the fauces, and the author considered the asthma and vomiting due to similar patches on the mucous membrane of the stomach and bronchial tubes.

(Asthma and urticaria are both sufficiently common affections, generally occur entirely independent of one another, and it seems highly fanciful to draw any inferences as to their connection from the fact that in a few instances the same individual suffers from them both simultaneously.—*Rep.*)

A patient of Dr. Thorowgood<sup>6</sup> has from boyhood been liable to attacks of spasmodic asthma, is now about forty, and finds that the presence in his room of a hare or its skin will bring on a severe attack: the smell of a roasted hare, however, acts as a still more speedily exciting cause.

(Medical literature contains many cases similar to the above in which asthma seems to be directly dependent on emanations from animals, feathers, etc.; and in many of these attacks never occur unless there is exposure to the special and peculiar irritant. It would seem that these cases must belong in a category altogether distinct from those in which Curschmann thinks the cause lies in exudative bronchiolitis.—*Rep.*)

#### OBLITERATION OF ONE LUNG, WITH DISPLACEMENT OF THE HEART.<sup>7</sup>

At the closing meeting of the Islington Medical Society, on the 26th ult., Dr. Glover gave the particulars and showed the specimens of two very striking lesions in the case of a man aged sixty-three, whom he had known for several years as a dispensary patient and otherwise. The most noticeable peculiarity was the complete displacement of the heart. It occupied the right side, and beat between the fourth and fifth ribs. This fact had been observed thirty-five years ago by Mr. Jackson, one of the oldest members of the Society, and the patient had been examined by many physicians, amongst others by Dr. Austin Flint, who came to the conclusion that there was no transposition of organs—a conclusion verified by the post-mortem. But the autopsy revealed another lesion, which was as remarkable as the malposition of the heart. This was the almost complete absence of the right lung. It had to be long sought for ere it could be found, and was then discovered as a very hard shrivelled substance, in shape something like a sausage. On being cut into, it was found to consist almost entirely of thickened pleura, the pleura being at points half an inch thick. The lung substance was nearly destroyed, not with intersecting bands of fibrous tissue, but by this envelope of thick pleura. The left lung was correspondingly large. No history of pleurisy could be traced in the patient's life, and no history of consumption in that of his family. He had always been weak and slight. His mother always had noticed "a heaving on the wrong side." He used to have severe bleedings at the nose. His chief troubles had been cough and rheumatism. He died in the Islington workhouse of broncho-pneumonia. It is common to say that a person has lost a lung, but here the statement was a literal expression of the fact, though the patient contrived to live without it, and with his heart on the wrong side, for sixty three years.

#### FATAL HEMOPTYSIS.

The statistics of the Victoria Park Hospital for fifteen years bearing on this point, were reported to

the Medical and Chirurgical Society, by Dr. West.<sup>8</sup> The cases were twenty-six in number, the rupture of the aneurisms other than those of branches of the pulmonary artery being excluded. In seventeen of the cases the cause was ascertained; in eleven it was aneurism: in six ulcerated vessel, the distinction between these lesions being probably only one of degree. Any cavity, whatever its origin or shape, might be the source of the bleeding, provided it were chronic; chronic phthisis was the predisposing condition of the lung, and that often when there were but few clinical evidences of the disease. The causes of non-fatal and of fatal hæmoptysis are probably the same, there being evidence to show that both pulmonary aneurisms and eroded vessels may heal spontaneously.

In discussing the paper, Dr. Percy Kidd said that he had made autopsies in thirty-five cases of fatal hæmoptysis. In thirty of these, death had been directly produced in a very short space of time; in the other five, the patients had survived for periods varying from one to twelve hours. In nine cases, where during life there had been no hæmoptysis, he had found aneurism of the pulmonary artery after death. The aneurisms, which varied in size from that of a hempseed to that of a small orange, were in his cases generally in the lower two thirds of the lung, and were not very uncommon even at the base. Some explanation of this might, he thought, be seen in the fact that this part of the lung moved most in relation with the diaphragm. He agreed with Dr. West so far as to believe that the cavity in which the aneurism formed was nearly always chronic; but not always, for he had met with three cases in which it was acute, and in all these it was at the base.

#### HEMPTYSIS TREATED BY THE INDUCTION OF PNEUMOTHORAX SO AS TO COLLAPSE THE LUNG.

Dr. Cayley<sup>9</sup> reports the case of a man of twenty-one years, a porter, admitted into the Middlesex Hospital for hæmoptysis: for some time past he had suffered from a slight cough but his health was otherwise very good, and the blood-spitting began only two days before admission. The feeble respiration, râles, and other signs detected in the left lung were attributed to the clogging of the organ with blood: the temperature was usually normal or subnormal in the morning, and rose to about 100° at night. For about three weeks the hæmorrhage persisted, and as life was evidently threatened by the loss of blood, it was decided after consultation to induce pneumothorax so as to cause collapse of the left lung and thus prevent the bleeding, which came probably from a pulmonary aneurism or an ulcerated vessel. The operation was accordingly done and a tube was inserted: during the night following the operation the patient spat up blood twice, four ounces and two ounces, but there was no return of the hæmorrhage: the patient died suddenly, apparently from syncope, five days after the operation.

The autopsy showed that the case was one of acute tuberculous with one or two small cavities of older date, and the blood came from a branch of the pulmonary artery communicating with one of these cavities. The cavity containing the clot was smooth walled, and showed no signs of any aneurismal sac.

<sup>6</sup> British Medical Journal, 1885, I, p. 278.

<sup>7</sup> Lancet, 1885, I, p. 1012.

<sup>8</sup> British Medical Journal, 1885, I, p. 126.

<sup>9</sup> Ibid., 1885, I, p. 991.

The nature of the case was such that, as it turned out, recovery was hopeless under any treatment. When the operation was done there was no special reason for suspecting that the case was one of acute tuberculosis; and, as regards the operation itself, Dr. Cayley thinks life was not sufficiently prolonged to allow a decision as to the direct effect of the procedure on the hemorrhage.

#### SEROUS EXPECTORATION AFTER TAPPING THE PLEURAL CAVITY.

Scriba<sup>10</sup> reports the case of a very anæmic young woman admitted into the hospital for general oedema coming on gradually after the middle period of pregnancy: premature labor was induced, but the oedema and dyspnoea increased rather than diminished, the patient was transferred to the medical wards, and a very large left pleural effusion was diagnosed. On the following day, 1,600 ccm. of slightly turbid serous fluid was slowly evacuated through a small trocar without the use of suction; but almost immediately after the instrument was withdrawn, severe cough came on with the expectoration of a frothy, light yellow fluid, which soon ran in a nearly steady stream out of the mouth, and surpassed a litre in amount: the rattling in the chest could be heard at a distance. Collapse appeared, the fluid diminished in quantity, and a few hours later the patient died.

The autopsy showed that the lung was in no way wounded by the operation, tuberculosis of the pleura and peritoneum with a few old cheesy nodules in the left lung, pulmonary oedema, and a fibrinous coagulum in the left primary bronchus filling its lumen and extending downwards into the second and third divisions.

The author then reviews other similar recorded cases, and the explanations of the mechanism of the fatal oedema which have been put forward. The only theory which he thinks explains all the facts is that of Leichtenstern, which is based upon experiments of Cohnheim, showing that the permeability of the walls of blood-vessels is increased, when for any reason the blood current has been prevented from flowing through the vessels for some time, a condition which is met by the pulmonary capillaries in cases of large pleuritic effusion. As soon as the fluid is withdrawn and the lung expands, abundant serous transudation may occur; and of this there is greater danger when, as in the case under consideration, the patient is very anæmic and the action of the heart is feeble.

If the above views are correct, they enjoin upon us to be very careful to avoid the rapid withdrawal of pleuritic fluid in every case; and, in cases of marked anæmia or weak heart, to take away only a small quantity at any one time.

#### ANTIPYRIN IN PHTHISIS.<sup>11</sup>

To quote the opening paragraph of Dr. Holland's paper: "For some years now I have had many consumptive patients under my care, in fact living under the same roof with myself, and the treatment of the febrile state in these persons has been the source of daily thought, indeed, I might say of daily anxiety. These placed in a similar position to myself must have noticed what has struck me forcibly, namely, for what reason can the consumptive's temperature will rise. A little extra exertion, a political discussion, an attack

of indigestion, a slight fall on the ice which has caused neither pain nor apparent injury, an attack of toothache—any of these things, which to a person in health might mean nothing, often tends in the sensitive phthisical patient to start a degree of fever which it is frequently difficult to suppress. Should the pyrexia continue for two or three days, we are almost certain to discover signs in the lungs of some fresh mischief; perhaps a little softening is detected over an area that had begun to dry up, or crepitation manifests itself in a part of the affected lung, where, after careful examination, it had not been noticed before. This form, then, is the first and earliest symptom of lung change, and must, in my opinion, be immediately attacked." He then goes on to say that after eight months' use of antipyrin he finds it more useful in combating the pyrexia of phthisis than quinine, the salicyl compounds, digitalis, aconite, kairin and Warburg's tincture all put together. He gives the drug in 15-20 grain doses every three or four hours at first, and diminishes the frequency as the temperature falls. The drug causes very little if any disturbance, and seems clearly to be of service in the cases which are reported.

(The systematic treatment of the pyrexia of phthisis is coming to the foreground, and is likely to receive impetus in this country from Jaccoud's work on the Curability and Treatment of Pulmonary Phthisis, recently published in translation by D. Appleton & Co. Jaccoud recommends quinine and the salicyl compounds against fever, the drugs being given hypodermically if the stomach is irritable: antipyrin had not been discovered when his book was written, and seems to possess the great advantage of being much better tolerated by the stomach than are the older antipyretics.—*Rep.*)

### Reports of Societies.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting June 18, 1885.

#### OBSERVATIONS ON THE OPERATION FOR LACERATED PERINEUM, WITH DEMONSTRATIONS AND CASES.

DR. H. W. MITCHELL read a paper on this subject. Having briefly reviewed the anatomy of the female perineum and the effects likely to result from its rupture, he expressed his doubts as to a satisfactory repair of the injury spontaneously, and went on to say that when the parts were torn, the proper thing to do was to restore them to their original integrity, and that this was possible by means of a simple operation, which could be performed by any physician of ordinary skill. He first spoke of the preparatory treatment, and then described the common operation of denuding the surfaces of the lacerated tissues and uniting them by means of deep silver wire sutures. Formerly he had been in the habit, according to the general custom among surgeons, of drawing the wires through by means of a silk loop; but more recently he had adopted the plan of threading the needle directly with the silver wire, and he considered this in every way preferable. He made it a point always to insert the finger into the rectum as a guide when passing the sutures. He thought it well to employ as few sutures as would answer the purpose desired. He employed a

<sup>10</sup> *Deutsche Archiv. für Klin. Med.*, 1. 56, Band 8, 1881, p. 329.  
<sup>11</sup> *Practitioner*, May, 1885, p. 331.

curved needle, and inserted and brought out the sutures through the skin at some little distance from the edges of the wound. Having secured the deep wire sutures by twisting them together with moderate tightness, he passed one or more superficial silk sutures to approximate the edges of the skin. The urine was drawn with a flexible catheter before the patient left the table.

As to the matter of antiseptics, he thought perfect cleanliness was all that was required in this operation. In five out of forty cases in which he had operated during the past fifteen months he had used carbolic water as a dressing; but in the other thirty-five had used no antiseptic whatever. He said that all the operations had been attended with complete success, and that union by first intention had resulted in every instance. The after-treatment consisted in keeping the parts scrupulously clean and the bowels confined for the first six days; the patient in the meanwhile living upon a light diet. On the sixth or seventh day the sutures were removed. In case there was also a laceration of the cervix requiring treatment, he operated on that at the same time as the perineum; the cervical sutures being allowed to remain until the eighth or ninth day. When the sutures had been removed the patient was permitted to get up; when she first did this it was sometimes found that there was a slight paresis of the lower extremities resulting from the want of action on the part of the muscles during the time that she was confined to bed. This usually lasted but a few hours, but in exceptional cases might remain for several days.

In all the forty cases referred to, it was the second-ary operation that was performed, and in nearly one half of the entire number there was laceration of the cervix upon which he operated also. It was his practice to sew up the cervix with the patient in Sims' position, and then to have her turned on her back for the perineal operation. In two of the cases the rupture of the perineum was associated with complete *prolapsed uteri*; one of the patients being seventy-six years of age, and the other sixty-five. In the case of the older of the two, before operating on the perineum he amputated the whole neck of the uterus, according to the method of Dr. Isaac E. Taylor; and in both instances a perfect result was obtained. One of the other cases operated on was that of a lady six months pregnant, who insisted on having the operation performed on account of the great discomfort which she experienced in consequence of the ruptured condition of the perineum, and when the ether was given her, the fetus in utero was also anesthetized, the effect of the drug remaining for several hours. This patient then went on to full term, and the new perineum stood the strain of the labor perfectly well. The most common cause of laceration of the perineum, Dr. Mitchell thought, was the incompetence and carelessness of midwives, who attend so many women of the lower classes in their confinement.

#### DISCUSSION.

DR. ALFRED C. POST said he thought it was wiser to keep the bowels open regularly after the operation, as it rendered the patient more comfortable and assisted in the satisfactory performance of the functions of the body generally. It was decidedly objectionable to have an accumulation in the bowels, such as would result from keeping them confined for six or

seven days, and he believed it was now the practise of the best gynecologists to see that after the operation the bowels were opened every day. As to the operation which Dr. Mitchell had employed, it certainly seemed to have been very successful in his hands; but for himself he preferred the plan, which he had described before the Academy a short time ago, of simple incisions (without denuding the mucous membrane), and then bringing the parts together by means of two flaps, one linking upwards and the other down toward the perineum.

DR. MALCOLM McLEAN said that he was surprised to hear the author of the paper say that he had discarded the silk loop. He believed it was much preferable to use the latter, and this procedure was almost universally adopted among gynecologists. At the present day the curved needle was decidedly antiquated. It was impossible to guide it with accuracy, and the short straight needle was used almost altogether in place of it. By elevating the parts it could always be inserted with perfect precision. Another point: when the sutures are inserted through skin as well as mucous membrane, a very serious amount of pain was almost invariably caused. Yet Dr. Mitchell had expressly stated in almost every instance in narrating his cases that the patient was free from pain after the operation, and he would like to know how he explained this.

DR. BARUCH said that he fully agreed with Dr. Post as to the advisability of keeping the bowels open. The old method of keeping them confined had now to a great extent been given up, and for this step in advance the profession was indebted to a gentleman of this city, Dr. Hanks. He also had the same objection to the curved needle that Dr. McLean had, namely, that it was impossible to guide it accurately. The author of the paper, however, certainly deserved credit for his attempt to simplify the operation as he had done, since it was highly desirable that every practitioner should feel himself capable of performing it whenever the occasion might arise. He was also glad to see that he condemned the doctrine that the perineum was in any sense a support to the uterus. On this subject he believed that Emmet's views were entirely correct. As to passing the sutures through the skin, he thought that this must necessarily be followed by more or less pain. It was like the operation of hemorrhoids before Alingham's method was adopted, when it was always requisite to use opium freely in the after-treatment. In Emmet's new operation for ruptured perineum all the sutures were within the line of the muco-cutaneous fold of the vulva, and it was followed by no pain whatever. While, however, Emmet's operation was, he believed, the best in many respects that had yet been devised, it was a difficult one to describe satisfactorily, and he feared, therefore, that it would never be as widely understood and become as popular as it deserved to be. In the operation employed by Dr. Mitchell very little of the rectocele seemed to be taken in, and while it was, no doubt, an excellent operation in comparatively recent cases, this, he thought, was a serious objection to it in many older ones. Still, the results in his hands, according to the reports which had been read, were very creditable to him. As to the discarding of the use of the silk loop, he could see no satisfactory reason for doing this.

DR. MITCHELL said in reply, that with the plan

which he had adopted, no inconvenience whatever was experienced from keeping the bowels confined. The night before operating he always ordered some efficient laxative, and in the morning this was followed by an enema. As the food taken during the days succeeding the operation was always of a very light character, there was consequently but little accumulation of fecal matter in the bowels. As to the reason why there was so little pain after his operations he could not say, but such was the fact; and he thought it was a mistake to suppose that the passage of the sutures through the integument necessarily gave rise to pain. In surgical procedures in other parts of the body it was very common to pass sutures through the skin, and yet in many of them this was not followed by any special pain. In regard to the curved needle he said that with the finger in the rectum he had found that its direction could be guided perfectly and without any difficulty, and he thought it was decidedly preferable to the straight needle. There was no necessity whatever for lifting up the parts with the tenaculum. When the silk loop was used in connection with the wire suture, a larger needle was required, and altogether he thought this procedure complicated the operation and made it more difficult. One great objection to Emmet's operation was, that it was not sufficiently simple, and his experience had shown that by this simpler one described in the paper, a torn perineum could be perfectly restored; which was the particular object in view.

DR. JOSEPH A. ANDREWS read a paper on

#### CONTAGIOUS CONJUNCTIVITIS.—ITS CAUSE, PREVENTION, AND TREATMENT.

He gave the report of a case of successful inoculation, made by himself, of the conjunctiva with a pure gonococcus culture of the ninth generation. It was not, however, in a healthy eye, the patient suffering from pannus and other troubles. Three weeks previously he had inoculated the conjunctiva of the same individual with a pure culture of a coccus found in healthy saliva, but with an entirely negative result. After the gonococcus inoculation, however, the eye presented a perfect picture of gonorrhoeal conjunctivitis.

Having given a *résumé* of the results obtained by other observers in similar experiments, he went on to speak of ophthalmia neonatorum. While the infection was often received directly from the vagina of the mother at the time of birth, he believed that more frequently it was contracted somewhat later and through other channels. It had been ascertained that normal loeidal discharge did not produce blennorrhoea. When a child was the subject of the disease, there was danger of its infecting the whole household, and it was necessary that great care should be taken to avoid this. In speaking of granular conjunctivitis, he said that Satter claimed to have produced this affection by inoculation; but in this he believed that he was probably mistaken. Personally he had not been able to find cocci of any kind in over fifteen hundred cases in which he had made careful search for them. The secretion was probably the carrier of the contagion, but it required special conditions, such as are liable to result from overcrowding, improper diet and bad hygienic surroundings generally, for its development.

A ophthalmia neonatorum was sometimes contracted directly from the vaginal secretions, it was advisable

that the parts of the mother should be very thoroughly cleansed before the birth of the child. When there was reason to fear infection, the eyes of the infant should be washed with a saturated solution of boric acid, and a two per cent solution of nitrate of silver also applied. Credé's method of prophylactic instillation had been followed with excellent results. In addition to the two per cent nitrate of silver solution, he used a solution of salicylic acid. Up to 1880, when he first began the practise, the disease attacked no less than ten per cent of all the infants at the Leipsic lying-in hospital; but since this plan had been adopted there had been only about one case a year, out of from three to four hundred children born. Dr. Garrigues for several months had had a two per cent nitrate of silver solution applied to the eyes of all new-born infants in the maternity hospital on Blackwell's Island, and out of 351 children, had not a single case of the disease. He did not state in his report, however, whether any of the mothers were infected. In Dr. Mundé's service at the same institution the two per cent solution was used upon eighty children, without a single case of the disease; while in Dr. Murray's service, in which a one per cent solution of nitrate of silver was employed, ten or twelve out of fifty infants were attacked. It was claimed by Credé and others that one per cent solution was not sufficiently strong to prevent the affection. Post-natal infection, as he had said, was in his opinion more common than infection at birth, and it was derived from the mother through the agency of sponges, towels, etc. In every case, therefore, when there was danger of infection it was best to keep the child entirely away from the mother except at the time of nursing. Ophthalmia neonatorum was a disease which prevailed principally among the poorer classes, and he believed that it was the duty of physicians to warn dispensary patients and others of its danger as they had the opportunity.

Dr. Andrews then spoke of the treatment of purulent conjunctivitis. The first thing to do was to wash away any infecting material, and the second to render the conjunctival surface as nearly as possible aseptic. Injections should be used for several minutes at a time, after which a two or four per cent of nitrate of silver should be applied. If the latter strength was employed, it was advisable to follow it with a solution of chloride of sodium, to neutralize it. Boric acid and vaseline made an excellent dressing, and iced cloths are to be kept applied to the eyes. If there was much swelling of the eye, the outer canthus should be cut. Dr. Andrews exhibited an eye speculum he had devised, which was made hollow, so that by attaching to it a fountain syringe, irrigation could be practised in a very satisfactory way by means of it. A three per cent solution of carbolic acid could be used in the case of adults. From four to twelve per cent solutions of nitrate of silver might be required according to the urgency of the case.

—The Criminal Law Amendment Bill has passed through the House of Commons with amendments, which will doubtless be accepted by the Lords. The important clauses raise the minimum age of "consent" for females to sixteen years. Copulation with a girl between thirteen to sixteen, even if with consent, is now a misdemeanor; below thirteen is a rape, punishable as felony.

## TRANSACTIONS OF THE CHICAGO GYNECOLOGICAL SOCIETY.

W. W. JAGGARD, EDITOR.

REGULAR Meeting, Friday Evening, 19th June, 1885. The President, DR. H. P. MERRIMAN, in the chair.

I. PROFESSOR J. H. ETHERIDGE read a report of a case of

## A FÆTUS ENCLOSED IN ITS SISTER'S PLACENTA.

(*Fætus Compressus. Fætus Papyraceus.*) With exhibition of the specimen.

On 26th September, 1882, Mrs. T. J. B., 22 years old, of a nervous sanguine temperament, healthy, was delivered of a mature female child, after a normal labor of four hours duration.

During the delivery of the placenta, some abnormality was detectable, which proved to be a *fætus papyraceus*.

## THE OUTER SURFACE OF THE PLACENTA.

The outer surface of the placenta at once arrests attention. A deep furrow separates the two placenta, which are united, on their amniotic surface, by a series of compact white bands, discoverable only by pressing through the furrow. The large placenta constitutes about two-thirds of the entire mass. The smaller placenta is thin, flat and compact, being about one-third as thick as the larger one.

The placenta of the living child is normal throughout its extent. Cotyledons are well marked, the tufts and villi presenting normal microscopical characters. The placenta of the *fætus compressus*, in about nine-tenths of its extent, is whitish-yellow, and very firm. The whole thickness of this portion of the placenta, excepting its amniotic surface, presents one unbroken mass of fatty degeneration. The remaining one-tenth of the placenta presents a carneous appearance, evidently a transition stage between normal placenta and complete fatty destruction. Its cotyledon are enmassed and its tufts and villi solidified and the whole is interspersed with initial fatty depositions.

## THE FETAL SURFACE OF PLACENTA.

The two segments were wholly different at time of birth. The placenta of the living child presented a normal appearance. The placenta of the *fætus papyraceus* presented the appearance of a closed bladder, which, upon examination, was found to be an unruptured amnion, containing amniotic fluid and a fetus. The development of the *fætus compressus* corresponded to the third month. The cord of the *fætus papyraceus* was ten cm. longer than that of its fellow, and much thinner. The cord was inserted into the margin of the placenta, near the fully developed organ.

*Pathology.*—Among the causes, producing the death of the fetus, the following may be mentioned:

- (1) Faulty insertion of the cord, at the margin of the placenta, adjoining its fellow. (Kieselhausen).
- (2) Faulty structure of the cord; thin, twisted, or deficient in the jelly of Wharton. (U. Braun).
- (3) Diseases of the placenta.
- (4) Traumatism.
- (5) The implanting of the umbilical vessels too closely together, and arterial anastomosis.

*Literature.*—*Fætus papyraceus* is of seldom occurrence. A search through the library of the Surgeon General's office at Washington resulted in finding only five references to reports of similar cases.

## DISCUSSION.

DR. PHILIP ADOLPHUS thought that such cases were of more frequent occurrence than the remarks of the author of the paper would lead one to believe. In twin pregnancy, the death of one fetus before parturition was not infrequent.

PROFESSOR W. W. JAGGARD agreed with Dr. Adolphus that while such cases were rare, a more extended research into the literature of the subject would have revealed a much larger number of cases. While it was true that American and English text-books usually merely mentioned the fact of occurrence, German, French and Italian treatises devote a chapter to the subject. The last edition of *Schroeder* contained an excellent *résumé* of the literature. The case, reported and exhibited by Professor Etheridge, resembled in many points the case in the Pathological Museum of the Jena Living-in Hospital, fully described by B. S. Schultze. This specimen showed the placenta of a mature fetus, and adjoining it a second egg, corresponding to the sixth week of pregnancy, with its own decidua and unruptured amnion. Professor Etheridge's case was chiefly interesting, as bearing upon a subject of theoretical importance, that is, superfecundation and superfetation. On *à priori* grounds, it was possible that superfetation could occur as late as the twelfth week of pregnancy, — when *decidua vera* and *reflexa* became united. Up to this time, it was possible that egg and spermatozoid might come in contact. Superfetation was also possible in cases of double uteri. Up to the present time, however, no case has been recorded which does not admit of a simpler explanation. There exists a great weight of evidence in favor of superfecundation. Mares give birth simultaneously to horse and mule foals; bitches, running during the period of rut with different breeds of dogs, throw young of different, so-called bastard forms, corresponding to the breeds of the male progenitors; the same is true of cats. A woman may give birth to twins, one of which is white, one black. The latter fact, however, does not necessarily demand for its explanation intercourse at or near the same time with a white and a black man, since in crossing races, the offspring may resemble either father or mother, or one child may resemble the male, the other the female progenitor.

There could be no reasonable doubt as to the accuracy of Professor Etheridge's diagnosis.

DR. JOHN BARTLETT had seen one case of *fætus compressus* in the Chicago Woman's Hospital, about four years ago. One fetus was mature, the other corresponded in development to the fifth month of pregnancy.

PROFESSOR BARTLETT referred to the contribution of Snellie and Mauriceau upon the subject.

DR. EDWARD WARREN SAWYER referred to the fact that in ectopic pregnancy no compression of the fetus was observed. He alluded to a case, in which he performed laparotomy three and one-half years ago. The fetus weighed eight pounds. There could be no question about superfetation in Professor Etheridge's case. Fetation by inclusion, might be considered as explanatory of many of the monstrosities which are so commonly seen.

PROFESSOR DANIEL T. NELSON thought it would be interesting to know how much force was necessary to compress the fetus as in Professor Etheridge's

specimen. He referred to the experiments of Professor Park, of the Massachusetts Agricultural College, in the determination of the expansile force of growing squashes and pumpkins.

The president wished to know whether the death of the fetus occurred before compression, or whether it resulted from that factor. The marginal insertion of the cord doubtless was an important etiological agent. When the uterus was in the pelvic cavity, compression was greater.

He referred to the fact that in twin pregnancies, it was unusual to find both children equally developed, and frequently the birth of one preceded that of the other by minutes, hours, and even days.

II. DR. HENRY T. BYFORD read a report of a case of

#### LEIO-MYOM OF THE VAGINA AND UTERUS.

The patient was a widow, about thirty-five years old. Was married ten years without becoming pregnant. She had no decided symptoms of disease except an occasional back-ache, some leucorrhœa. She was treated for uterine inflammation three years before, and no tumor was discovered. Since that time she has menstruated every two weeks. Catamenia usually lasted five days, and were normal as to quantity.

Twelve years ago she noticed a tumor about the size of a hickory nut just within the vagina. This swelling had since that time grown steadily, until its protrusion from the vagina, about the 12th of January, 1885, caused great inconvenience. Even at that time, the pain was promptly relieved by an opiate, administered by Dr. Doering. Two or three days subsequently, the tumor became black, swollen, and emitted a gangrenous odor. Slight septicæmia followed cauterization with nitric and carbolic acids. The tumor was attached to the anterior wall of the vagina.

The tumor was subsequently crushed off, and the patient recovered. Indagation revealed a protuberance, about the size of a goose egg, upon the right anterior surface of the uterus, which was apparently a leio-myom.

The following points of interest are to be noted in connection with the case:—

- (1) The occurrence of both tumors in the same person.
- (2) The slow growth of the vaginal as compared with the uterine tumor.
- (3) Sloughing of the capsule, immediately after protrusion from the vagina, without impairment of the vitality of the tumor, proper.
- (4) Entire absence of sensitiveness to strong acids.
- (5) The production of a pedicle by ligaturing the proximal end with a fine wire.
- (6) Sterility, antedating the discovery of the uterine tumor.
- (7) The influence of ergot upon the uterine tumor.

#### DISCUSSION.

DR. EDWARD WARREN SAWYER thought that the locality of the vaginal tumor was interesting but not unusual.

PROFESSOR DANIEL T. NELSON inquired whether or no fibroid tumors occurred by preference in the anterior vaginal wall.

He thought, as regards the operation, an elliptical incision around the base, and enucleation of the tumor, would have fulfilled the indications equally well.

The Society then adjourned.

## Recent Literature.

*Endemic Goitre, or Thyreocoele being the Thesis for the Degree of Doctor of Medicine of the University of Durham, for which the Gold Medal of the Year 1884 was awarded, together with subsequently added Footnotes and Appendix.* By WILLIAM ROBINSON, M.D. M.S. London: J. & A. CHURCHILL. 1885.

Until quite recently the thyroid gland has been supposed to have no important influence on the bodily functions. Since, however, Professor Kocher of Berne pointed out that in many cases the total extirpation of this gland was followed by serious disturbance of nutrition, and that this condition was closely allied to myxoedema, the thyroid body has come to be regarded as occupying a most important place in the animal economy, and to be in intimate relation with the central nervous system. Within the past two years there is probably no portion of the human body that has received more attention both from practical surgeons (Kocher, Reverdin, Bruns, Baumgarten, etc.) and experimental physiologists (Zesas, Credé, Sanguinico, Canalis, Schiff, Horsley, etc.) than the thyroid gland. The way the matter stands at present seems to be about as follows: the condition described long ago by Sir William Gull under the name of "a cretinoid state supervening in adult life in women," the "myxoedema" of Ord, the "cachexia strumipriva" of Kocher, and "cretinism" are identical affections. Destruction of the functions of the thyroid gland by disease is a cause of cretinism, and after its complete removal man becomes a cretin. To quote Mr. Horsley, the gland consists of two distinct parts: one glandular, secreting mucus, the other lymphoid, and hematogenous in function. Its excision is followed by profound blood changes; an increase in the amount of mucus in the tissues; increased activity of the muciparous glands; and the secretion of mucus by glands which usually yield none. Nervous symptoms also occur, namely, muscular tremors, rigidity and paresis, imbecility, and ultimately coma followed by death.

The statement has been made that goitre is increasing in this country, and it will be interesting to hear from American surgeons, — who have so far remained silent — upon this important question of the effect of extirpating the thyroid gland on the general system.

Dr. Robinson's thesis is admirably printed and gotten up, and he presents the subject in a clear and most interesting manner.

F. H. H.

*A Treatise on Abdominal Palpation as applied to Obstetrics, and Version by External Manipulation.* By A. PINARD. Translated by L. E. NEALE, M.D. 8vo., pp. 101. New York: J. H. Vail & Co. 1885.

This monograph is a translation of that part of the Classic work of Pinard, which relates to abdominal palpation as applied to obstetrics. After a short introduction on the determination of pregnancy by external examination, the various presentations and positions of the fetus are considered seriatim, and the methods of diagnosis by palpation carefully described with the aid of frequent illustrations. The pages on the diagnosis of multiple pregnancy are especially valuable. The sensations afforded by palpation in cases of hydramnium, of death and neceration of the fetus, and of hydatiform mole, also receive considerable attention.

In the second part of his work the author describes

the means to fix and engage the fetal head during the latter period of gestation, and the definite transformation of the presentations of the shoulder and of the breech into presentations of the vertex during the same period. After considering the history of cephalic version by external manipulations, the author clearly describes the method of operating and of subsequently maintaining the changed position and presentation by means of a properly fitted abdominal support. The propriety of correcting presentations of the breech into those of the head has never been acknowledged by obstetricians of note, with a few exceptions. Pinard, however, the weight of whose authority must be universally admitted, thoroughly believes in the procedure, except in certain specified cases. Experience has taught him that in breech presentation, cephalic version is possible before the engagement of the pelvic extremity, and is moreover not dangerous to either mother or child. Whereas, as is well known, the fetal mortality in cases of breech presentation is about ten per cent.

The value of manipulative skill in the diagnosis of pregnancy and of fetal position and presentation by external examination is appreciated by all who have seen in large foreign hospitals the success with which it is practiced; and Dr. Neale has now made it possible for all English speaking medical men to be thoroughly acquainted with the methods to be pursued and the objects to be accomplished. The few typographical errors will doubtless be corrected in a second edition.

*The Ear; its Anatomy, Physiology and Diseases: a Practical Treatise for the Use of Medical Students and Practitioners.* By CHARLES H. BURNETT, A. M., M.D. Professor of Otolaryngology in the Philadelphia Polyclinic, etc. Second Edition, Revised and Rewritten. Phila.: Henry C. Lea's Son & Co. 1881. 8vo, pp. 585.

This second edition differs from the first chiefly in the chapters on abnormalities of the Auricle, Otitis, Otitis, the Treatment of Chronic Otorrhea, the Classification of Aural Polypi, the Diagnosis, Etiology and Treatment of Aural Vertigo, which have been entirely re-written and which are made very satisfactory. In other subjects, however, there has been added here a little and there a little, and this with the application of the pruning knife to certain dead branches has brought the work thoroughly down to time, and it is now one of the best arranged and scientific of the many treatises on the ear, prominent, however, as heretofore or its anatomy and physiology. It is a thoroughly safe guide to the practitioner. The only possible criticism is that in attempting to do full justice to the literature of some of his subjects the author has been possibly a little too encyclopaedic in his treatment for a practical treatise.

—Dr. Hermann v. Boeck, Professor of Pharmacology in Munich, has died at the age of forty-two. Also the death is announced, at the age of forty-six, of the well-known physician for children's diseases in Buda-Pesth, Dr. Faludy.

—Dr. Partington after reading of the wholesale withdrawals from the International Medical Congress, as at present governed, was heard to remark sententiously, that he feared the congress was likely to be merely a sexual one.

## Medical and Surgical Journal.

THURSDAY, AUGUST 27, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

### SURGERY OF THE LUNGS.

MORE than two years since (March 15th, 1883), the JOURNAL published a letter from Dr. G. L. Walton, written from Berlin, giving some details of experiments upon animals — rabbits, swine, dogs and cows — in resection of portions of lung. Dr. Black had previously read a paper before a meeting of the German Surgical Congress upon the subject, and when Dr. Walton met him he was exhibiting his results at Virchow's laboratory. These results upon animals had been quite successful, and though performed without very strict antiseptic precautions, and without resection of the ribs, had proved safe in most cases. The difference between such operations upon animals and upon man, upon healthy and upon diseased lungs, was dwelt upon by those present at Virchow's laboratory, but Dr. Black was very sanguine, and not long after operated upon the lung of a young woman, with a fatal result. The lung was found to have been healthy, a prosection was instituted, and the operator committed suicide.

We are reminded of these occurrences by the receipt of an essay in French on the "Surgery of the Lung in non-traumatic Affections," by Dr. N. True of Lyons, in which, by the way, the credit of Dr. Walton's communication is given to the Edinburgh Medical Journal. The writer considers his subject under the heads of pneumectomy (resection), pneumotomy (incision), and intra-pulmonary injections. He has gone over the literature of the subject pretty thoroughly on the ground that the advances in antiseptic surgery of recent years and the comparative impunity with which other greater cavities are opened and other important organs are handled, makes a revision of experience and teaching upon this question desirable.

The only reported instances of resection of lung, beside Black's ill-fated case already referred to, are two by Krönlein of Zurich, upon tuberculous subjects, one of whom died nine days and the other a few hours after the operation; two by Ruggi, of Bologna, also upon tuberculous subjects, one apex in each case being affected, the first of which died on the ninth day of carbolic poisoning, and the second after thirty-six hours,

the lung in this case having been closely adherent to the plura; one case by Dr. Milton of Georgia, who, after resecting two carious ribs, removed two-thirds of one lobe of the right lung, for what affection is not stated, this patient lived four months; Krönlein and Weinleucht have each removed portions of lung involved in tumors of the chest wall, the former with a successful, the latter with a speedy fatal issue.

Biondi gives the following *résumé* of his operations upon animals:

	Operations.	Success.
Extirpation of the right lung	23	12
" " left lung	54	18
" " both apices	3	3
" " middle lobe	1	1
" " lower lobe	1	1

Dr. True arrives at the judicious general conclusions in regard to pneumectomy that a partial or total resection, performed antiseptically, is generally supported by most animals and is compatible with life; that applied to man in the treatment of tuberculosis the operation has hitherto given deplorable results; that directed against secondary cancer, the affection of the lung being superficial and circumscribed it may be useful and less dangerous.

Pneumotomy, with and without drainage, a procedure of a very respectable antiquity, is considered as applied to (a) simple abscesses and bronchiectasies; (b) to tuberculous abscesses; (c) to pulmonary gangrenes; (d) to hydatid cysts; (e) to foreign bodies. A large number of observations are cited under these various heads, and the general conclusions are reached that incision of the lung, for well determined cases deserves a recognized place in surgical practise, and may be regarded as advantageous (a) in certain abscesses of various origin entailing grave phenomena and whose topography is well established; (b) in circumscribed gangrene producing general infection the situation of which can be made out; (c) in putrid bronchitis when severe and localized; (d) in rare forms of limited tuberculosis accompanied by exhausting septic infection; (e) in hydatid cysts of large volume without spontaneous cure and resisting other methods; (f) in cases of intra-pulmonary foreign bodies not amenable to the usual manipulations and giving rise to inflammatory disturbances.

Exploratory punctures, when made carefully, are harmless and often give valuable indications for pneumotomy; pleural adhesions are not always indispensable, but are a favorable condition, and their absence in certain cases should be a formal contra-indication to interference; the lancet may be used, but the thermocautery, which is less dangerous, should be generally preferred; resection of the ribs ought to be more generally practised, especially with large pulmonary cavities, drainage and anti-septic washing-out are always useful and often necessary.

In regard to intra-pulmonary injections, Dr. True concludes from his review of the literature of the subject, that anti-septic injections into cavities without pneumotomy do not promise well; injections into the pulmonary parenchyma are well borne both by man

and animals if carefully administered with but slightly irritating liquids in moderate doses; intra-parenchymatous injections in tuberculous subjects neither aggravate the local condition nor arrest the course of the pulmonary lesions, and in some cases seem to have produced a slight amelioration of the symptoms; various regions of the chest wall may be traversed, but the sub-clavicular and the axillary are the safest and handiest.

## THE ARGUMENT AS TO CONSANGUINEOUS MARRIAGES FROM THE LOWER ANIMALS.

THE important question which is the subject of a contribution on another page of the JOURNAL, is one which in the human subject must always be difficult of solution, on account of the many complicating circumstances which are present in every case of consanguineous marriage, and because of the impossibility of controlling the experiments. For this reason particular interest attaches to the study of the effects of inbreeding in animals. The objection against analogies so drawn, that animals coupled by breeders are selected for their freedom from defects and are therefore not fairly representative of what may be expected from human unions, is faulty for the reason that as bearing on the influence of consanguinity it is just those cases when all extraneous influences as those of morbid inheritance are shut out that give the best opportunity for judging fairly of the effect of consanguinity as a factor.

The opinion of Darwin is well known, that all beings, animal and vegetable, profit from an occasional cross with individuals not kindred in origin. There can be no doubt in any mind that when once taint or degeneration has begun to develop in an animal the only salvation for the offspring of such an individual lies in the obliteration or mitigation of the defect through the admixture of a blood free from any similar imperfections, such a result being attained with the greatest certainty in an individual having no kinship with the one affected. The chance in nature that animals and plants by continually uniting with individuals near, by propinquity and relationship, will fail to obliterate, and will in fact intensify any incipient abnormality, is so great that nature has provided, notably in the great order of orchids, for a system of cross fertilization by the mediation of insects. Yet in some variety of orchids and in many other plants self-fertilization is the rule. Incestuous unions among animals in a natural state are by no means uncommon.

When through the intelligent selection of the stock-breeders the animals brought together are both perfect specimens, even though closely related, the offspring is not only free from deterioration, but often presents an intensification of the good points of his progenitors. This was, in fact, the means by which Bates, Bakewell, the brothers Collings, and other famous English breeders developed some of the most remarkable breeds of cattle.

The criticism has been made by some writers that those various created breeds of animals are, after all, abnormalities — "perfect pathological specimens," as Mitchell puts it — not so useful to themselves as their less highly bred fellows. Of course various points may be selected for which to breed, for instance, either wool or flesh in sheep, draught or speed in horses. An excessive development of fat, as in a prize pig, may impair not only the physical symmetry, but the power of locomotion and of procreation. But that animals are necessarily deteriorated by being bred for some particular point is by no means true. The most eminent authorities agree that for endurance of work no horse can beat the thoroughbred.

There is, we are aware, still a dispute among cattle-raisers as to the desirability of long-continued in-and-in breeding, some claiming that such animals will sooner or later "run out" unless crossed. Into this controversy we do not propose to enter. We will simply state that it has been the custom of many breeders to mate animals which presented the desired qualities, irrespective of what is considered the accident of their relationship. Moreover, as importers often start with a single pair, the strain is procreanted without any outside intermixture, as is done by Price in the case of his excellent breed of Herefords. This breeder did not go beyond his own herd for a bull or a cow for forty years. Of course, when any organ or function in the stock is becoming developed at the too great expense of the others, the in-and-in breeder, like any other, will find it necessary to reinforce the defective side, and a cross becomes necessary, simply because the desired variation can no longer be found in the same family.

The most important point to be borne in mind in considering the results of in-breeding in animals is that the closeness of the unions is out of all comparison with that attained, or by any possibility attainable, in the human subject. The long period of childhood in man, to say nothing of moral and social considerations, would prevent his ever being united in such closeness of consanguinity as that in which animals are constantly mated. The child of first cousins has 25 per cent of the blood of his parent's common ancestor. The child of brother and sister has 50 per cent. The man who commits incest with his own daughter can transmit to the child of such a union only 75 per cent of his blood. Yet the herd books are full of cases of animals having 50 to 75 per cent of the blood of progenitor. The great majority of the descendants of the noted Jersey bull, St. Helier, have more than 50 per cent of his blood, several have 75 per cent, and one has 87½ per cent. Huth records that the bull Bolingbroke was mated with his half-sister Phoenix and produced the bull Favorite. Favorite mated with his mother, sired the cow Phoenix (2<sup>nd</sup>). He was then put successively to his daughter, daughter's daughter, and daughter's daughter's daughter, he being the sire in each case. This gave a cow which had no less than 93¾ per cent

of Favorite's blood. She was put to a bull having 62 per cent of Favorite, and the offspring was Restless, an eminent breeding cow.

The history of the Jersey breed, formed on a small island no larger than a western farm, and kept rigidly from all foreign mixture, is well known to all. This in-breeding was directed to one end, namely the increase of the butter yield, and while a fair production from a good average cow is four pounds of butter per week, a Jersey cow has recently produced more than ten times that weight of butter in seven days. Of course such a forcing of one function is attended with risk, but who will say that as a whole the purest specimens of the Jersey breed are lacking in intelligence, health, or fertility?

Mr. Campbell Brown, recently writing in regard to the enormous proportion (some 40 per cent) of the class of 230 trotting horses which are directly descended from one horse, Rysdyk's Hambletonian, and speaking as a disbeliever in in-and-in breeding, says that the above horse was not himself highly in-bred, having but 25 per cent of the blood of another great stallion, and adds, that this is "a degree of in-breeding to which there can hardly be rational objection." This per cent is precisely that which first cousins transmit to their children of the blood of their common ancestor. Whether then we hold with the one, and that a large and growing school of stock-raisers, that the closest incestuous breeding of animals may be practised for many successive generations without evil results, or whether we adopt the entirely conservative view that at least the lower degrees of in-breeding, involving a duplication of blood to the extent only of 25 per cent, are to be safely practised, the inference from the analogy of the lower animals would seem to be that in the human species an occasional union between first or second cousins is likely, so far as concerns the single fact of consanguinity, to give rise to no deleterious results.

#### THE PRESENT STATE OF MEDICAL EDUCATION IN THE UNITED STATES.

MEDICAL education is so frequent a topic for discussion in medical journals, that one must feel sure that he has something worth saying if he expects to find a reader for anything he dares to inflict upon his medical brethren. But though discussed so often by medical men among themselves it is not often treated as a subject of general public interest in periodicals addressed to general readers. The last number of the *Popular Science Monthly* has an article on the present condition of Medical Education, which treats the subject rather from a general educational than from a strictly professional standpoint, and though the author, Dr. William Gilman Thompson, has little to say that is unknown to the profession, his method of presenting the subject is worthy of repetition and consideration. He considers that public sentiment and action are aroused in regard to all manner of sanitary and curative measures. Pop-

ular works abound upon every medical topic. The germ theory has given a great impetus to popular medicine. The germ appeals to the average mind; it is something tangible which may be hunted down, and held directly responsible for so much damage. Much of this popular medical talk is the result of an earnest desire to learn to alleviate the growing evils of heredity and environment, especially in over-crowded cities. There is a wide-spread popular interest in the training of nurses, in the establishment of diet kitchens, and instruction in "first aid to the injured."

All these activities, directed toward improving the public health and alleviating sickness and suffering, are most gratifying and commendable, and call for increasing thoroughness in methods of educating physicians, for, without the coöperation of the public with scientific men who devote their lives to the study of these subjects, much benevolent energy as well as time and expense are wasted or misapplied. Is it not clearly of vital moment that the public for its own protection should see to it, by legislation or other means, that the medical schools of this country are of the highest order? A dozen well-trained and properly qualified physicians will be of vastly more benefit anywhere than a hundred "M.D.'s" who have slipped through some of our so-called medical "colleges" in the easy manner that is still quite possible. It is disgraceful, and yet it happens constantly, that men are graduated by prominent medical schools or colleges in this country without ever having listened to an abnormal heart-sound, seen a case of measles, or been present at a confinement. "But," it is asked, "why should the general public take any interest in medical education? Why not let doctors manage their own 'shops,' as they always have done, unaided by public support?"

The answer is that, so long as a medical college is dependent entirely upon the fees of its students for support, the highest educational good cannot be attained. The question concerns endowment, and the statement of a few facts will demonstrate this need.

With our present population of fifty millions we have eighty-seven medical schools (the irregular schools are not included in this enumeration). Of these schools thirty-nine have been opened within fifteen years, and twenty-one within five years. With them are associated 1,300 instructors and over 10,000 students, and about 3,600 new doctors are annually "turned loose on the community."

Forty-six per cent of these schools offer only a two years' course, and practical work is for the most part optional. A little dissection, a thesis and examinations upon the lectures are all that is required in many colleges, before receiving a diploma. There are fortunately a few colleges where a much higher standing is required. The reason why so many of our students annually go abroad to Paris, Berlin and Vienna is that they can join small classes where they can practically demonstrate every fact for themselves under the guidance of an instructor.

But practical work means increased expense. There

needs to be laboratories for chemical, physiological, anatomical and pathological research, rooms for photography and for the reception and treatment of patients at clinics. Increased expenses mean higher charges with the risk of seeing students leave for cheaper and easier colleges. Thus lack of endowment is a check upon all growth.

General Eaton, the Commissioner of Education, strongly advises that every medical school or college, be required by law to procure forthwith an endowment of not less than \$300,000. A certain amount of endowment required by law would prevent the formation of new medical colleges without proper laboratories, apparatus, or facilities of any kind. To-day the value of income-bearing funds of the eighty-seven medical colleges does not exceed \$350,000, with an annual income of about \$20,000. The precarious footing on which these institutions stand is to be inferred from the fact that fifty-one medical schools and colleges have ceased to exist within a century.

It is a grave misfortune that so many medical colleges now exist, for it is a farce to attempt to educate medical students away from the hospitals and dispensaries which only the largest cities furnish in abundance. The tendency to-day in all branches of education, is more and more toward placing practical work and personal observation before tradition and theoretical instruction. Medical education should not be left behind in facilities.

The article is a timely one, and in most respects a wise one, but the difficulty is but partly told when the lack of endowments, or the need of State examinations, which our author also mentions, is specified.

There is a deeper reason in the wide-spread belief that so much study is superfluous. There is no longer any public opinion which compels a man to fit himself for any duty. The old time apprenticeship is not demanded for the artisan, and if men are too often only anxious to select that school which will allow them in the shortest time to earn their living as physicians, the public are only too ready to look with favor on the young man who by some trick has gained a diploma in a shorter time than even the short time required.

## Miscellany.

### THE DISSENSIONS IN AMERICA.

THE present medical situation in the United States has received less attention on this side the water than it deserves. But we may assure our American readers that all here who have mastered the question sympathize most deeply with them in the trouble that has befallen them. A disagreement like the present is, for many reasons, taken more to heart by our American kinsman than it would be in England, assuming for the moment such a schism to be possible here. The American temperament differs perceptibly from ours.

It is less insular and phlegmatic, more sensitive, we fancy, to the opinion of other countries, more concerned to make a good appearance before the world. Then the position of the medical profession in America is somewhat different from that which it holds in this country. Here we take a comparatively inferior place in the social hierarchy; we are over-shadowed by estates and professions of higher importance and prestige in the nation's estimate. Our organization too is more oligarchical: there is more reverence amongst us for authority. Our leaders do lead, and if they are unanimous in any undertaking, as in the case of the London Congress, being able to count on the support of Royalty, and the City, and South Kensington, and other depositories of power, they can afford to be indifferent to the support of the mere privates in their army. Even if the Editor of the *British Medical Journal* and all his Council had made up their minds to control the London Congress or to wreck it, they would only have made themselves ridiculous. But in the United States the position of the profession is entirely different. There is nothing to overshadow it there. It holds a position as important and honorable in the State as that of any other calling; so that an International Medical Congress in America may be expected to enjoy a higher dignity from a national point of view than it can claim in older countries; but, at the same time, it must depend far more largely for its ceremonial success on the harmonious co-operation of the medical profession itself. Now in the United States, the organization of the profession is purely democratic; there is no common link like that of our Royal Colleges, no recognized headship like that of our President of the College of Physicians, or our President of the College of Surgeons. According to the very political theory on which the State is founded, every man has as good a right to lead as any other, if he can only get that right admitted by his fellows, and for that purpose one vote is as good as another. Distinction in science and reputation abroad supply no reason to a practitioner in Texas or Colorado why he should follow a Wendell Holmes or a Weir Mitchell, in preference to a Shoemaker or a Beverly Cole. Hence a revolt of the "rump" in the United States threatens to prove a much more disastrous affair than it would be in England, and hence we especially ask our readers' sympathy for those well and widely known American practitioners, whose title to lead their profession is admitted everywhere except in the ruder and remoter States of their own country.

We have had an opportunity of seeing several letters from distinguished American practitioners, and they all concur in expressing the most bitter grief and disappointment at the pass to which their profession has been brought. In these letters we have met with scarcely one word of anger against the dissidents who have rudely torn up the first programme of the Congress. Indeed, if we may say so without impudence, the spirit in which the "leaders" of the American profession, for we still venture to call them so, have met the recent crisis is one which reflects the highest possible credit upon them. We hardly know which to praise most, their patient suspension of action until the Chicago meeting had confirmed the spirit of the proceedings of the meeting at New Orleans, or their swift and unanimous protest and withdrawal from the Congress when definite action was at length called for. The only hope for the Congress — the only possibility

of maintaining the dignity of the profession — lay in such firm and united action on their part, and the effect of this action has been so favorable that there already appears to be a much more hopeful feeling in the States as to the prospects of a peace with honor. The organizers of the revolt are meanwhile making frantic efforts to prevent further resignations, and are even said to contemplate throwing over Dr. Shoemaker, on the score of his supposed unpopularity. But we may take it that no concessions on their part will be accepted short of unconditional surrender and full recognition of the authority and acts of the original Committee. These are the essential preliminaries to the holding of any International Congress at all, and every day increases the prospect of their general acceptance. The sooner they are accepted the better. There will then be still two years in which to bury the hatchet, two years in which to prepare a Congress which shall "whip creation." We had all made up our minds for that, and shall be disappointed with anything less — *The Medical Times and Gazette*.

#### GASTROSTOMY IN LEYDEN.

IN the *Lancet*, (August 8th), we find an extract from notes of two interesting cases in which gastrostomy was performed by Professor van Iterson of Leyden. The first case was that of a gentleman, aged fifty, who had carcinoma of the œsophagus, and who had been unable to swallow any food for several days before the operation, and was consequently reduced to a state of great emaciation and debility. The abdominal wall was opened and the stomach fastened to it, arrangements being made for supporting life by means of nutrient enemata until it should be thought safe to open the stomach. Collapse, however, came on shortly after the operation, and death supervened. The Professor says that if he had another similar case he would open the stomach at a single operation. The second case was more satisfactory, and was that of a painter, aged fifty-seven, who suffered from a circumscribed tumor affecting the supra-scapular region, the neck, pharynx, œsophagus and larynx. When seen in July, 1884, he had had difficulty in swallowing for about a year, the last four months of which time he had been unable to take any solid food. A small bougie (No 27 Charrière) was with great difficulty passed through the stricture. The first part of the operation was performed on the 16th of July under an anæsthetic, with antiseptic, but without spray, and consisted in opening the abdominal wall, lifting aside the liver, seizing the wall of the stomach as high up as possible, and attaching it with ligatures very carefully to the abdominal wound. This was dressed with powdered iodoform and salicylic wool. The patient was supported by nutrient peptonised enemata for six days, when an opening was made in the stomach with the galvanocautery, sufficient to admit the end of a three-quarter centimetre India rubber tube; the other end of this was provided with a funnel. At first, liquid nourishment was administered through this; then solid food was chewed in the mouth and spat into the funnel, the India rubber tube being thus an artificial œsophagus. The patient expressed himself as well satisfied by this method of feeding. He left the hospital three months after the operation. Two months later (November) he re-

turned, complaining of dyspnoea from obstruction of the larynx. Tracheotomy was performed, and a month later it was noted that his daily nourishment consisted of five slices of bread, two eggs, one cup of soup, one beer-glass of port wine, one ounce of raw beefsteak with potatoes, greens, and rice, and one litre of milk. Two months later, or eight months after the operation, the malignant tumour increased considerably, and hæmorrhage occurred, which in a few days induced a fatal termination of the case. At the autopsy the stomach was found attached to the abdominal wall for about the size of the surface of a dollar. The fistula was 70 millimetres to the left of the cardia, 240 from the pylorus, and 40 from the insertion of the omentum. The mucous membrane was pale, but healthy; above, the stomach was found adherent to the diaphragm. Professor van Iterson remarks that few cases have lived eight months and a week after this operation. He agrees with the advice given by other surgeons that the opening into the stomach should be as far as possible from the pylorus. In both cases he was able by means of a sharp hook to bring the most suitable portion of the stomach to the wound.

## Correspondence.

### SPONDYLOLISTHETIC PELVIS.

BOSTON, AUG. 23, 1885.

MR. EDITOR.—In my article on "Spondylolisthetic Pelvis" published in the last number of the *Journal*, p. 172, seventh line from the foot of the column, "Parderbörner's case" should read "the Parderbörner case."

Since this paper was written, I have come across an extremely interesting and exhaustive article on the subject by Neugebauer.<sup>1</sup> In addition to the nine cases collected by Schroeder, Neugebauer reports twenty-two other cases, seven of which were confirmed by autopsy, the remaining fifteen resting on clinical observation. One of these occurred in San Francisco and was reported by Blaque.

As a result of his investigations Neugebauer states,<sup>2</sup> "Spondylolisthesis is to be looked upon as a surgical deformity which though occasionally developed where there has been a congenital anomaly in the ossification of one of the vertebrae "is almost always of traumatic origin."

Very truly yours,

F. H. LOMBARD, M.D.

### THE COUVEUSE AND GAVAGE.

MR. EDITOR.—If the French nation, in its frequent foreign wars and internal revolutions, has shown itself indifferent to the waste of human life, in its more pacific state, when its destructive passions are not aroused, it seems to manifest a remarkable interest in conserving it.

Attenuating circumstances serve as a plea for the mitigation of the death penalty in most of the capital cases, no matter how great the enormity of the crime, as though there was the greatest reluctance on the part of their fellow countrymen to put out of existence even its most worthless and dangerous members.

A recent exhibition before the Academy of Medicine in Paris of the successful results of certain experiments, made by one of its members, will perhaps serve to substantiate

this statement. In the French journal "*Le Temps*" of the 23rd of July an article under the head of "*Deux phénomènes*" is published, of which the following is a hasty translation.

"This is not the first time that success has attended the attempt to preserve the lives of infants born prematurely; but it must be acknowledged that M. Tarnier has made these attempts much more rational and efficacious by the employment of two new methods, the incubator [*couveuse*] and what he calls *gavage* or artificial feeding.

"The incubator takes the place of the thick covering of cotton batting in which it was usual to wrap the frail being too early brought to light. Although in this way the surface was warmly protected from the surrounding air, its too low temperature would frequently irritate its delicate lungs. The incubator is maintained at a uniform temperature of from 85° to 95° Fahr. The artificial nourishment is administered by means of a rubber tube provided with a glass vessel, into which the food is poured; the best is of course the mother's milk. This tube is passed through the oesophagus into the stomach. As soon as the liquid poured into the glass at the end of the tube has been delivered into the stomach the instrument must be immediately withdrawn.

"M. Tarnier exhibited to the members present two nurslings, born six weeks ago, and which, having begun to feed from the breast, may be considered as saved, or at least as having survived the most dangerous period of their growth.

"During the first three days, eight grammes of milk were given them every hour. On the fourth day they were fed every three hours with sixteen grammes. In this way the feeding has been continued, increasing gradually the amount of food and the intervals between its administration. These infants were born in all probability near the commencement of the sixth month or the end of the fifth. One weighed at birth 1,020 grammes; it fell off to 850; it now weighs 955 grammes. It was red, and its body transparent and extremely limp. The other, a little stronger, weighed 1,100 grammes; it now weighs 1,500 grammes. M. Tarnier, with a just pride, exhibits his nurslings to the Academy. Spite of their incredible diminutiveness (they may easily be held in the hollow of the two hands), they manifest their vitality by their movements and cries."

H. E. D.

Malaga, July 24, 1885.

### MEDICAL STUDY IN GERMANY.

VIENNA, July 17, 1885.

MR. EDITOR.—It is not a particularly grateful task to compare the advantages offered by Berlin and Vienna respectively to foreign students; yet it is of great importance for physicians who go abroad to study, to know where they can employ their time and money to the best advantage.

There is no little feeling in the two centres as to the relative merits of the respective schools, and it would not be too much to say that the Berliners, having acquired military and political supremacy in Germany and Europe, are disposed to take it for granted that scientific hegemony belongs to them also, and to slightly resent assumption of equality elsewhere.

Naturally enough this feeling does not tend to increase the comfort and equanimity of the professional world, and there is considerable acerbity of feeling discoverable, not only in Vienna, but in other German cities.

As Vienna is the only city, however, which as a whole can compare with Berlin as a medical centre, it is the only one which seems to inspire any jealousy, or which it is necessary to damn with faint praise. And so one hears frequently in Berlin that Vienna has lost ground, that their scientific and medical men do not work there hard enough, that they spend too much time in the cafes, that they only work for money and not for science, that living in Vienna is extremely dear, etc., etc.

The imperial government and the state and city are all doing their utmost to make Berlin the medical centre, not only of Germany, but of the world; money is really lav-

<sup>1</sup> *Zur Casuistik des sogenannten Spondylolisthetischen Beckens*, Archiv für Gynäk., Bd. 3, Heft 1, 2.

<sup>2</sup> Loc. cit.

ished on the new hospitals, and the inner furnishing and arrangements are superb.

It is no secret that this extravagant (for Germany) support of medical institutions has its political reasons, nothing less than the desire and intention on the part of the authorities, to make Berlin the centre of intellectual and professional activity for all Germany, a centre to which all the youth desirous of the highest education shall be drawn, and where they shall learn to know and respect the power and majesty of the new Empire. And precisely because in medicine, if in nothing else, the superiority of the new Empire is not so evident as could be wished, the above extraordinary exertions are made to assist it. Need I say that the desires of the government are ably seconded by the profession? And as virtue is not always rewarded in this world it is satisfactory to know that a stream of patients seeking consultations and laden with fees comes from all Germany and even from America: much of this used to go to Vienna, much that would be welcome in Berlin yet goes to Vienna.—“*hinc ille larynx*.”

Now in respect to the foreign physicians the case is something like this; while recognizing the great distinction of the Berlin teachers, and the fact that much can be got as a matter of courtesy there, which must be paid for in Vienna, yet they flock to the latter place. There they can concentrate their energy and work all day in one place, whereas in Berlin the hospitals lie so far apart that men get tired in moving from one to the other, and lose time by having to wait for hours with nothing in particular to do.

This is not only the case with those who are studying several specialties, and a little of everything, as most of the recent graduates do, taking up whatever they have not learned well at home; it is also largely true of those who are working on one subject, for the Berliners have not taken the pains so to arrange their special courses that they do not conflict as to time.

So that after a few weeks, or a couple of months in Berlin, most of the American physicians find their way to Vienna, and when they get settled and at work they stay as long as they can. And yet a course of study in Berlin is absolutely necessary to a complete study of almost any subject. Nowhere else can surgery be seen so thoroughly antiseptic, in principle and detail, and such facilities for observing not only the operations but all the dressings; for the latter are done not in the wards but in the operating-room, or in a place arranged on purpose. It seems amusing at first, for instance to see Professor Hahn, at the new hospital at Friedrichshain, operating, or overseeing the dressing of wounds, with rubber boots on, while the tiled floor is always wet, being actually flushed off with a hose after each operation.

While speaking of Professor Hahn I will mention a series of cases to which I think not much attention has been called at home, and that is of cases of ulceration of the rectum, occurring usually, but not always, in women, not syphilitic, or tuberculous or cancerous, but yet progressive, incurable, and always fatal by marasmus, unless cured in the early stages by complete destruction of the diseased surfaces.

I saw Professor Hahn operate for such a case in a young woman, a prostitute, by thorough use of Paquelin's and the actual cautery. I also recently saw an autopsy on a similar case in Vienna.

The ulcers look like chancroids, but are not autoinfectious, and so far as is known after much experiment and reflection are supposed by Professor Hahn to be of gonorrhoeal origin, in which opinion he is held in Vienna to be correct.

Hahn has had some thirty or forty cases, as since his first article on the subject many have been sent to him; all modes of treatment have been tried and found equally useless, except as above mentioned; probably many cases considered as syphilitic disease of the rectum are really of this nature. In many of the cases it could not be shown, and in some it seemed hard to believe, that there was any introduction of the gonorrhoeal virus other than accidental, that is by secretions flowing down over the anus. In most, however, a direct infection was admitted.

In regard to the other disparagements of Vienna mentioned above, they are simply erroneous, at least as far as Americans are concerned.

I dare say that a roosting-place such as will satisfy some students, and a chance to live on certain kinds of food, can be found cheaper in Berlin than in Vienna, but for men who wish to live as well as they do at home, in good rooms and good beds, eating good food, and plenty of hot meat, Vienna is just as cheap. At least I found it so, and I could get more comfort for less money here than in Berlin.

In regard to the medical men, it would be fair to say that the assistants through much teaching neglect original investigation, and that when they teach they expect to be paid for it. Now this is quite natural; the demand for instruction has produced a supply of excellent teachers, who are hard workers, usually speak English and French, as well as German, and possibly one of the other languages. They make no claims to be investigators, in laboratories; they are clinical workers and clinical teachers. There are also investigators in Vienna, but the foreigners see little of them, and on the whole probably they do not get so much support and encouragement as in Berlin. But as an example of patient exhaustive scientific work I will mention Professor Kundrat's studies concerning congenital malformations and monstrosities, patient labor going on now for years, with most elaborate dissections, descriptions, drawings by himself, and publication. And so one who looks for it finds the original work, but most "care for none of these things."

In regard to fees for instruction, to me they seem eminently proper. To be sure, in the smaller German cities, in England, and largely in Berlin, also, a man who is polite and knows how to ask for and receive a courtesy can get a great deal of clinical instruction for nothing, and at first it is rather a shock to see that he is expected to pay for the same in Vienna. But where there are two or three hundred foreign physicians, all seeking clinical privileges, and many hardly willing to be civil in their manner of asking, patience soon ceases to be a virtue. The demand on the time of the assistants and docents is so great, that either they must close their doors to applicants, or make their clinical instruction a matter of business. As a matter of fact, Americans prefer to ask for what they want, get it promptly, and pay for it, rather than to be always asking for favors, receiving courtesies, and knowing that they are a source of inconvenience to the donor. That, however, also in Vienna a spirit of professional courtesy exists, and of kind instruction of foreigners, clinically gratis, if they know the language and come at proper times, I cheerfully and gratefully bear witness.

The work of the German Imperial Health Office is too celebrated to need comment, except the wish that we could have such work done by such a body at home.

There is an idea prevalent in Berlin, perhaps not universal, that not much is known or taught about bacilli and micrococci, of any great value, outside of that city, and any divergence of opinion from that of the great Koch is simply rank heresy. There is, however, a decided scepticism in some quarters on the question of the comma bacillus as the efficient cause of cholera, of which I will say more in another communication, merely saying here that it is rumored that the late cholera commission in Rome, of which the proceedings are not yet published, was not as much disposed to accept Koch's views as had been expected. The short courses on cholera in the Health Office will no longer be held by Koch in person, I believe, as he has undertaken the duties of professor in the university, teaching bacteriology.

It was with some surprise that I found more opportunity to get courses and practical work on bacteria in Vienna than in Berlin. There are at least three laboratories and moreover two courses of lectures, without laboratory work, open to foreign students in Vienna, and there are some advantages in studying the subject there as a part of practical pathology.

The glory of the Vienna school has long been in the in-

timate relations between pathological anatomy and diagnosis, and under the present able management there is no danger that the school will lose its renown. The concentration of picked cases from the whole Empire in one vast hospital makes it easy for the physicians in charge, as well as for those studying here, to follow up every fatal case at the autopsy. Professor Kundrat, the successor of Rokitsky, has greatly enlarged the pathological institute, and with incredible labor has arranged, classified, and increased the pathological museum, so that it is now the finest in the world.

The autopsies can be seen by all, and ten foreigners can carry on practical microscopical work in an adjoining room, learning to handle, stain, and cut all sorts of morbid tissues. Upstairs, besides the chemical, histological, and other laboratories, and the museum and library, there is a bacteria room, where three or four can work, studying, breeding, and making preparations of the various micro-organisms.

Both of these rooms are under the able management of Drs. Kolisko and Paltan, the efficient assistants of Professor Kundrat, and it adds greatly to the interest of the work to be able to follow up cases from the wards to the autopsy room, and thence to examine microscopically the pathological condition of the diseased organ, and in suitable cases to catch the bacteria in the act, so to speak, to breed them, isolate them, and prove their pathogenic power by inoculations on animals.

In this way all the phlegmonous inflammations, erysipelas, pyæmia, puerperal and typhoid fevers, pneumonia, etc., can be studied on the spot, as well as tubercle, gonococcus and syphilis.

In connection with the subject of bacteria, I will mention that spray does not seem to be used at all here, either in surgical operations or laparotomies, which are done in the amphitheatres before the classes. A pretty close observation shows that very few cases die of sepsis or infection, where it is conceivable that the use of the spray, or of the extraordinary precautions as to those present at operations, in vogue in Berlin, could have made any difference.

And yet occasionally a case occurs where a greater thoroughness in precaution might have made a difference. For example, I saw fifteen laparotomies done within twelve days by Carl Braun with only one death, and that where a great sarcomatous tumor of the ovary had been removed. Yet shortly before in a case where a uterine fibroid with a well defined pedicle was simply removed per vaginam, by the use of the galvanocautic wire, the patient died, and in the uterine veins was put containing staphylococci. Of course some one must have brought them there, and when I add that just before the operation the patient had been examined by twelve or fifteen persons, mostly students, it is not hard to guess how the cocci got into the wound.

Some one had not used the nailbrush enough, some one had lied as to his handling of pathological specimens, and when the ———— cocci were once lodged well up in the uterine cavity the irrigator did not wash them out, and the iodiform did not chase them into the tissues.

There is a considerable difference of opinion here concerning the safety of the use of iodiform. Braun uses it in powder, very freely, blowing twenty to fifty grains on to the surface of a wound, or into the cavity of the uterus, and using also uterine suppositories containing two to three drachms each. Braun claims that this is quite safe, and at any rate must be employed, as the risk of intoxication is minimal compared with that of sepsis.

Billroth is afraid of iodiform, never uses it in powder, and seldom in pencils, but uses it in the form of iodiform-gauze, which is stuffed into the wound or cavity. His theory is that in this way there is little danger of intoxication, a very little of the drug comes in contact with the absorbing surface, while on the other hand, all the secretions are absorbed by the gauze and kept aseptic.

That is the only way in which iodiform is used in Billroth's ward, and it is supposed to be perfectly safe and entirely efficacious.

Yours respectfully,  
E. W. Cushing.

Announcement for 1885-86 of the Medical and Dental Departments of National University, 1004 and 1005 E Street, N. W., Washington, D.C.

An Address on Cholera Infantum. By William Perry Watson, A.M., M.D., Jersey City, N.Y. Assistant to the Chair of Diseases of Children in the New York Polyclinic. (Reprinted from the Archives of Pediatrics.)

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING AUGUST 22, 1885.

DRENNAN, M. C., surgeon. To temporary duty at Annapolis, Md., as member of Board for physical examination of candidates for admission to Naval Academy.

SIMON, WM. J., surgeon. To temporary duty at Annapolis, Md., as member of Board for physical examination of candidates for admission to Naval Academy.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 15, 1885, TO AUGUST 21, 1885.

CAMPBELL, JOHN, colonel and surgeon. Granted leave of absence for one month.

JONES, FRANCIS J., first lieutenant and assistant surgeon. (Recently appointed.) Ordered for duty in the Department of the Platte. S. O. 184, A. G. O., August 13, 1885.

WOLFEKTON, W. D., major and surgeon. Granted leave of absence for twenty days. (Washington Barracks, D.C.) S. O. 171, Department of the East, August 14, 1885.

MAYS, L. M., captain and assistant surgeon. In addition to his other duties, assigned to duty as attending surgeon of the Department Rifle Camp. S. O. 83, Department of Dakota, August 3, 1885.

BLACK, C. S., first lieutenant and assistant surgeon. Upon return of troops F. and L. 31 cavalry, to Fort Davis, Texas, to rejoin his proper station, Fort Clark, Texas. S. O. 98, Department of Texas, August 13, 1885.

McCAW, W. D., first lieutenant and assistant surgeon. Having reported back at these headquarters, from detached service, ordered to rejoin his proper station, Fort Lyon, Colorado. S. O. 122, Department of the Missouri, August 17, 1885.

## OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING AUGUST 22, 1885.

BALDWIN, P. H., surgeon. Granted thirty days leave of absence, August 15, 1885. Chairman of Board to examine candidates for appointment as Cadet, in the Revenue-Marine Service. August 19, 1885.

JEWIS, FREDMAN, passed assistant surgeon. Recorder of Board, August 19, 1885.

## Lecture.

## CHANGES IN THE BLOOD-SUPPLY OF THE BRAIN.

BEING THE SUBSTANCE OF LECTURES DELIVERED AT THE HARVARD MEDICAL SCHOOL, AND A CHAPTER FROM A BOOK NOW IN PRESS.

BY S. G. WEBBER, M.D.

*Instructor in Diseases of the Nervous System, Harvard University.*

## CEREBRAL ANEMIA.

AMONG the conditions of the brain most difficult for diagnosis are those in which there is irregular blood-supply. There are several reasons for this: 1. An over-worked brain is an exhausted brain; not only are the proper cerebral nervous elements exhausted, producing irregular action, but the vaso-motor nervous supply also may have become irregular from exhaustion of the vaso-motor nerves. 2. Another cause for mistake is that a badly nourished brain is irritable. Hence many of the symptoms of exhaustion and of malnutrition resemble those found in congestion or stimulation from excess of blood. 3. Poor blood, that which is not suitable for nourishment, may be sent in large amount to the brain, and there will still be practically anemia; the nervous structures may have lost their power of absorbing the nutrient materials from the blood, and the same results follow.

Under anemia it is intended to comprise all those conditions wherein there is insufficient nutrition of the brain, owing to defect in quantity or quality of the blood.

## ETIOLOGY.

When there is general anemia or chlorosis, the brain usually suffers more or less from an insufficient supply of healthy blood. Those conditions, then, are causes of cerebral anemia which give rise to general anemia, as hemorrhages, deficient supply of food, bad hygienic surroundings, exhausting discharges, whatever causes a poor appetite or poor digestion, etc.

A hindrance to the flow of blood to the brain, as pressure on the arteries, obstruction of their caliber by atheroma, arteritis, spasm, embolism, thrombosis, may give rise to a deficiency of blood-supply in the brain as a whole, or their influence may be local, and limited to a small area. The same result follows a weakening of the heart's action, so that the blood is not sent with sufficient force to fill the cerebral vessels.

Deficient oxidation, absorption of poisons, over-heating by sun or artificial heat, hyperpyrexia in fevers, etc., cause a defect in the quality of the blood, rendering it unfit for the healthy nutrition of the brain.

Though not immediately acting upon the supply of blood nor its quality, it is necessary to consider the conditions under which the patient has lived. Not only do anxiety and worry, but overwork, mentally or bodily, and loss of sleep, by exhausting the nervous system, have a tendency to give rise to an irritability of the brain, which causes it to show the effects of deficient blood-supply more quickly.

There are very few cases where diminished blood-supply alone is the cause of the symptoms. It is only in the acute cases following sudden hemorrhage that this is true, and even in these there is subsequently deficient quality of blood. Generally, changes in quality concur in causing the symptoms. Some of the diseases in which the symptoms of cerebral anemia may be

found, caused by changes in the nutrition of the blood, are dysentery, diarrhoea, gastric catarrh, phthisis, suppurative diseases, syphilis, typhoid and other fevers, and malarial poisoning.

## PATHOLOGICAL ANATOMY.

There is simply paleness of both white and gray substance, comparative emptiness of the blood-vessels, and, excepting there be compression from some cause, moisture of the cut surface. The lymph-spaces are filled with serum or lymph to compensate for the diminished fullness of the blood-vessels. In chronic cases there is, undoubtedly, change of nutrition; but our means of examination do not enable us to recognize such change.

In local anemia from obstruction of blood-vessels, changes occur which will be more properly considered elsewhere.

## SYMPTOMS.

The symptoms vary according as the anemia is acute or has come on gradually. If the patient has been exhausted by previous disease, the symptoms will be less violent than if he has been in vigorous health. Whether the brain has been overworked and excited must also be taken into consideration.

When a rapid hemorrhage causes cerebral anemia, the attack is acute, there is a loss of mental power, vertigo, dimness of sight and of hearing, tinnitus, sensation becomes blunted, the pupils are contracted, then dilated, the skin is cool, consciousness is lost, and convulsions occur. Respiration is accelerated, then slow; pulse small, frequent, and of diminished tension. This combination of symptoms may be seen not only in severe hemorrhages, as in surgical and obstetrical practice, but less completely developed where a patient greatly exhausted rises from the bed too suddenly; also in ordinary fainting from whatever cause.

The description of more chronic forms of cerebral anemia is rendered difficult by the fact that very few cases are uncomplicated. Nervous exhaustion, from anxiety, worry, fatigue, or overwork of brain, serves to intensify or change the symptoms; also the symptoms of anemia and hyperemia of the brain are very similar—so similar that it is oftentimes impossible to decide which condition is present without regard to preceding circumstances. Again, an irritable brain, anemic as a whole, may be locally congested, or may receive temporarily an increased supply of blood, though a supply below that appropriate for health, and, owing to its abnormal irritability, be excited, as if hyperemic.

In chronic anemia, thought is an effort, sustained mental exertion is impossible, memory is uncertain, the patient is drowsy; occasionally after rest there may be flashes of brilliancy, but they are brief. If effort is absolutely necessary, the patient may have learned that a very small amount of wine or spirit is a temporary aid. Headache is one of the most annoying symptoms, and is very persistent, and may incapacitate for the ordinary duties of life. After lying down long and being quiet, the headache may be relieved, but recurs on attempting to go about. Perhaps, in part owing to the headache, in part owing to the malnutrition of the nerve-centres, there is likely to be a change of disposition; irritability of temper, fretfulness, and peevishness are seen. Sometimes there is dizziness; more frequently there are noises in the head, tinnitus aurium, also various disturbances of vision, musca

volitantes, dimness, even amaurosis, though the latter is rare. Respiration may not be much changed, but there may be a feeling of discomfort, as if not air enough were inspired, and so there is sighing. The pulse usually varies only slightly from the normal, unless there is present some disease to account for an increased rapidity, as phthisis. The same is true of the temperature; it is usually about normal or a little below, but may be elevated if any febrile affection exists. General weakness is almost always seen, but rarely complete paralysis. Convulsions are not seen in cases of chronic anæmia.

When the anæmia is very great, there may occur delirium; if the anæmia has come on with moderate rapidity in a rather vigorous person, without previous disease, the delirium is usually active, the patient may even be maniacal, and may have hallucinations, hearing voices, and holding conversations with imaginary persons; he may not recognize his friends, or may desire to escape. This feature of cerebral anæmia has so much the appearance of excitement from hyperæmia that many refer it to such a condition, supposing that there is local congestion; but the active delirium is seen only when the affection has been developed rather rapidly, and is probably owing to the state of irritable weakness, to which reference has already been made. When the anæmia occurs during the course of an exhausting disease, either as a result of the disease or of insufficient feeding, the delirium is more likely to have a quiet character. Finally, the mental powers may be entirely lost.

#### DIAGNOSIS.

In forming a diagnosis of this affection, it is necessary to take into consideration the previous circumstances of the patient. The diagnosis from hyperæmia may be very difficult, and, as the treatment would be quite different, it is important to be as nearly correct as possible. If there is a history of long-continued privation, with worry and anxiety, or of hard work, physical or mental, and loss of appetite, or exhausting discharges, it is probable that the condition is anæmic, although there may be much excitement. It is sometimes more difficult to decide, where there is active delirium, whether it is insanity or anæmia. Here, also, the previous history will be of assistance; but, as anæmia may lead to change of structure in the nerve-cells, it may pass over into insanity, and without mania it may pass into melancholia. In insanity induced by cerebral anæmia there is not a long-continued period of excitement; the condition is rather one of depression, with occasional attacks of irritability.

To recognize that delirium in febrile diseases is owing to cerebral anæmia is all important. Especially in children with gastro-intestinal affections the symptoms resemble those of serious organic brain disease; the previous history must not be overlooked; it would be disastrous to treat a child with anæmia for meningitis. During typhoid fever in adults there may be a similar mistake. It would seem that care in watching the patient—not only the fever, but also the feeling of the patient—might prevent such an error. Excessively high temperatures may give rise to symptoms similar to those of anæmia; a careful use of the thermometer will guard against this mistake.

#### PROGNOSIS.

If there are no serious complications, as cardiac or Bright's disease the prognosis is favorable, provided

sources of exhaustion can be removed. The prognosis in the case of other disease may be favorable for the anæmia, though unfavorable for the primary disease.

#### TREATMENT.

If the case is one of acute anæmia, or of extreme weakness after protracted disease or exhausting discharges, it will be very important to keep the head low; perhaps the foot of the bed should be raised; the body should be kept warm, by artificial means if necessary; stimulants may be necessary; food in a form easily digested, in small amounts, frequently repeated.

The chronic form needs methodical rest and feeding. As many of the symptoms are due to exhaustion of the nervous system, the effort should be made to withdraw the patient from all such influences as tend to exhaust him. In many cases the course of treatment recommended by Weir Mitchell in "Fat and Blood" will give excellent results. In every case the best tonic is food. The food must be easily assimilated, not in too great quantities, and should be taken at short intervals. Milk is one of the best to begin with; not only is it easily digested and contains all the constituents of the body, but is largely composed of water. Fothergill's remarks about water in anæmia are deserving attention.<sup>1</sup> Among drugs, arsenic, iron, and quinine are valuable.

When there is restlessness, sleeplessness delirium, it may be necessary to give chloral and bromide of potassium, or paraldehyde. Small doses of these are worse than useless; even if frequently repeated, they are not efficacious; less than twenty grains of each is not sure of giving rest; in many cases it may be necessary to give thirty or even forty grains at one dose. Yet chloral should be given with caution, and not administered every time a patient does not sleep; it is often given injudiciously. Spirit will sometimes aid sleep. Opium is a valuable agent, and may often be given to advantage in small doses—a tenth or twelfth of a grain—the object being rather to obtain its stimulating effects. Sleep may sometimes be produced by a grain or two of quinine at bedtime, or by a dose of phosphoric acid, or by a light lunch just before retiring. A cup of bee-tea during the night may overcome the habit of lying awake.

#### CEREBRAL HYPERÆMIA.

When the arteries are distended; or there is an increased flow of blood through them, there is active hyperæmia; when the veins are over-distended, it is passive. The latter condition may, in reality, be one of anæmia, so far as concerns the state of the circulation in the brain.

Some authors deny the existence of cerebral congestion.

#### CAUSES.

Probably a predisposition to cerebral hyperæmia is constitutional with some persons, just as some blush more easily than others; the predisposition may be acquired. Whatever has a tendency to cause a fullness of the cerebral arteries, and keep the blood flowing rapidly through the brain, may give rise finally to a predisposition to cerebral hyperæmia. Excessive and often-repeated emotional disturbances, excessive and protracted brain-work, are among these agents. But it must be kept in mind that these also produce ex-

<sup>1</sup> "Handbook of Treatment," pp. 51, 52.

haustion, and so irritability, which may lead the brain to respond unhealthily to the normal amount of blood, or to be excessively excited by less than the normal amount.

Among other influences may be mentioned a low temperature: thus, most cases are said to occur in winter. A very high temperature is also said to cause congestion, and especially if the sun shines directly upon the head; but the symptoms following such exposure are rather due to elevation of temperature and change in the quality of the blood.

Increased activity of the heart is also said to be a cause of cerebral congestion; hence violent exertions may give rise to it.

Certain drugs may cause cerebral hyperæmia, as nitrite of amyl. Opium and belladonna have been thought to do so; but this is not certain. Alcohol may act as a cause, but only acutely; chronic alcoholism acts rather by producing changes in the quality of the blood, and so changes in the nerve-structures.

Malarial poison may excite congestion of the brain; indeed, probably every attack of chills and fever is attended with cerebral hyperæmia, and this may be one cause of danger in severe malarial diseases.

Passive congestion may be caused by any interference with the return of the blood from the brain.

#### ***PATHOLOGY.***

In acute cases very little change may be expected; much or most of the blood drains off post-mortem. Yet even then, and with rather more frequency in cases of long standing, the smaller vessels in the cerebral substance show with unusual distinctness upon section. The surface of the section is thickly sprinkled with bloody points, the gray substance is darker, and the white substance may have a decided pinkish color, from the fullness of the minutest vessels. In chronic cases the constant dilatation of the vessels may lead to changes around them; the perivascular sheaths may contain granules of blood pigment. There are seen, also, cavities in the brain containing the transverse section of a vessel. These are thought by some to be caused by dilated perivascular sheaths, by others to be dependent upon dilatation of the vessels. The latter may act as one agent in their production, another may be shrinking of the cerebral substance, a slight atrophy which causes a dilation of the perivascular sheaths.

Constant and repeated hyperæmia must interfere with the nutrition of the nervous structures; the high blood-pressure is unfavorable for the interchange of elements. The changes thus resulting occur slowly, but finally may be very serious and may lead to insanity. These changes will also explain why it often requires so long a time for recovery from symptoms which seem insignificant. In this connection it must be remembered that not only do the proper structures of the brain suffer, but also the walls of the blood-vessels and their vaso-motor nerves undergo changes — at least functional changes, and probably slight organic changes.

#### ***SYMPTOMS.***

Many of the symptoms of cerebral hyperæmia are the same as are found in cerebral anæmia, and many which are usually ascribed to hyperæmia are quite as dependent upon exhaustion from overwork, anxiety, etc. It is impossible to entirely separate the two classes of symptoms in giving an account of the affection.

If not severe, there may be a sense of heaviness, or pain in the head, with tinnitus (though this is more common in anæmia), dizziness, sleeplessness, more or less agitation, perhaps at times a tingling sensation in the fingers or feet, as if they were "asleep." These symptoms at first recur only occasionally, but may become more permanent.

There may be more serious symptoms: the temperament may be changed and the patient be fretful and irritable, the mental power diminished, and there may be absolute inability to apply the mind in certain directions. When an intense application of the mind to one class of questions has brought on the affection, there is inability to apply the mind in that direction. A teacher cannot teach; the effort to do so may cause such confusion that he will have no command over his speech; or a lawyer may be unable to try a case before a jury, the attempt to do so being preceded by sleepless nights, and accompanied by such distress, or even semi-delirium, as to make it impossible. It would seem as though in these cases there is a local irritability of the nerve-centres relating to such pursuits, which, when an attempt is made to use these centres gives rise to an increased flow of blood not only to them, but to other parts of the brain also. It is interesting to note that the use of other centres has not this effect: thus, the lawyer who cannot try a case in court may be able to attend to other business (though it is not by any means safe to allow it); the merchant may not be able to keep the run of his goods, but he can attend to his garden and care for his country residence without distress.

Memory is affected: there is confusion, dullness, wrong words are used in talking; there may be delirium, or the excitement may run into mania. At times there may be weakness of the limbs, twitching of muscles, especially of the face; paralyzes almost never occur; convulsions belong rather to anæmia or epilepsy; and also disturbances of sight and hearing are more frequent in anæmia; vomiting is rare. Respiration is little affected; the pulse is usually full and resistant, perhaps rapid, possibly moderate. The face is usually flushed or ruddy, is rarely pale, and the conjunctivæ may be injected.

Many authors describe a form of this affection attended with convulsions, which, however, Trousseau refers to epilepsy, and this explanation is now generally accepted.

There is a condition which I have met a few times which seems to be dependent on congestion rather than anæmia. I have only seen it in women run down nervously; so nervous exhaustion is one element in causing it. The patient, after some emotion or shock, only slightly more severe than usual, or after some exertion, as ascending stairs, feels weak, is unable to stand or sit, has distress in the head, then loses all power of motion and speech; lies as if in a faint, but the face is flushed; the heart beats vigorously, perhaps not more so than normal; respiration is little, if at all affected. If the attack is not severe, the patient may lie utterly helpless, unable even to move an eyelid, yet know all that is said and done. In severer cases, consciousness is lost. I have known such an attack to last two or three hours. There is no spasmodic action. Recovery is gradual, then respiration may be sighing; subsequently there is great distress in the head and confusion of thought for several hours.

These attacks may occur during the night, either in

consequence of a dream or from the previous day's exhaustion and the recumbent position. One gentleman told me that, after learning that his wife had these, the peculiar respiration, in her case noisy, aroused him. These attacks differ from epilepsy in that a definite cause can be so frequently traced that it is reasonable to think such a cause always exists; they recur as irregularly as the causes which give rise to them.

#### DIAGNOSIS.

It is not always easy to distinguish congestion from anæmia or from simple nervous exhaustion. Sometimes it is necessary to suspend judgment for a while to watch the course of the symptoms. A superficial examination of the patient will be as likely to lead to an error in diagnosis as to give correct results.

Some physicians recognize hyperæmia in almost every obscure morbid functional state of the brain; others disbelieve in it entirely.

The previous history of the patient will assist materially in diagnosis. Has the patient been well fed, or poorly? been happily situated, or miserably? had prosperity or poverty? have there been exhausting drains upon the system, frequent small hemorrhages, or severer hemorrhages? Is the patient full-blooded or generally anæmic? Is the face ruddy, flushed, or pale? Did the attack come on as the result of excitement, or during the strain of some intense mental effort, or during a violent physical exertion? All these inquiries will assist in forming a correct diagnosis when the symptoms are uncertain.

A diagnosis depending upon the symptoms may be made in many cases with some degree of probability. In anæmia, the symptoms are those of excitement only in rare cases, and then the excitement is not of long duration; as a rule, in the more chronic cases there is depression. In hyperæmia, excitement and exaltation predominate, and there is apparent depression only when the brain is overpowered by the severity of the attack, or the congestion is passive. The headache is more acute in anæmia; more of a feeling of painful fullness in hyperæmia. The pulse is fuller and more bounding in hyperæmia. These peculiarities, with attention to the whole group of symptoms as described above under both these affections, will, in most cases, lead to a correct diagnosis. It would be easy to pick out typical cases of both these conditions from actual practice and describe them, but such cases are not easily mistaken, and, unfortunately, form only a small proportion of the cases we see. As in many other diseases, a careful examination and consideration of all the circumstances are necessary to a correct diagnosis.

Other affections which must be separated from cerebral congestion are cerebral hemorrhage, cerebral embolism and thrombosis. These will be better considered under these affections. Vertigo from disease of the ear and from derangement of the digestive organs also needs to be distinguished.

The most important affection, next to anæmia, to correctly recognize is epilepsy. Some forms of epilepsy are so obscure, especially in the commencement of that affection, that it is no uncommon circumstance to have it overlooked, and the patient, his friends, and perhaps the physicians, consider the attack is a mere passing rush of blood to the head. This will be more intelligently considered under epilepsy.

A reasonable care in the examination of the urine

will suffice to distinguish Bright's disease, which may give rise to symptoms closely resembling those caused by disturbance of the cerebral circulation. The urine should be examined more than once if the diagnosis is doubtful.

#### PROGNOSIS.

The danger from an attack of cerebral congestion depends upon the severity of the attack and its suddenness. The brain may be completely overpowered by the sudden influx of blood, consciousness may be lost, and, if the medulla is also affected, life may be extinguished at once or very soon. Walter Moxon, however, finds no satisfactory post-mortem evidence that acute congestion is ever a cause of death.

But generally the patients do not die at once, and in chronic cases there seems to be no immediate danger to life. Recovery, however, is tedious. Almost always there have been various circumstances in the patient's history acting as predisposing causes, and this is one reason for the slow recovery. Where there is no complication, a recovery may be expected in time, provided the patient will submit to proper treatment.

Among other complications, the most unfavorable is organic change in the nervous elements of the brain. This may give rise to insanity.

#### TREATMENT.

Congestion of the brain may be accompanied with so severe symptoms, with such immediate danger to life, with unnatural fullness of the arteries, with such strong action of the heart, that general bleeding is indicated. These cases are, however, rare, and such bleeding would not be advisable in any except a robust and plethoric patient. Local bleeding by cups or leeches would be beneficial in a larger number of cases. In the severer forms, when it is not desirable to withdraw blood, means may be taken to increase the flow of blood to distant parts of the body, as by hot foot-baths or mustard foot-baths; or to diminish the amount of blood by acting on the bowels, saline cathartics, croton-oil, etc.; or by promoting copious sweating by hot-air baths, steam-baths, hot-water baths, keeping ice on the head. *Laborandi* acts especially on the skin; but as it frequently gives rise to violent vomiting, it would be hardly safe, lest the straining in vomiting should increase the congestion.

Cold applications to the head—ice, a rubber tube coiled up, with cold water running through it, evaporating lotions—may give relief; but to be of much benefit, the application must be continuous.

When there is violent delirium, mania as one of the most marked symptoms, it will be frequently found that there have been circumstances tending to render the brain excitable. The measures already mentioned may be employed; sometimes a wet cap to the back of the neck taking a few ounces of blood aids in giving relief; sometimes a dry cup gives equal relief. Bromide of potassium and chloral, in doses sufficient to produce sleep, are especially indicated; from thirty to sixty grains of each. Small doses of chloral repeated hourly have no effect, but rather aggravate the symptoms, and the combination of the two drugs is more efficacious than either alone. Hyoscyanum will often procure sleep and quiet if given in large doses. In cases of mania from cerebral hyperæmia, opium should not be given, but during delirium from anæmia it may be beneficial.

Where the hyperæmia is chronic and has been produced by excessive mental application, or by constant emotional excitement, the first indication is to remove the cause. The patient should drop his studies, his business, whatever has intensely occupied him, and withdraw from all associations which give rise to emotional disturbance. A quiet, regular, systematic life, with easily digested, mild food, is the most favorable. Bromide of potassium, without chloral, fifteen or twenty grains, three times a day. Bromide of sodium, lithium, calcium, or ammonium, have been used instead, and are more agreeable to some patients. Ergot, either as fluid extract, half a drachm to a drachm, or ergotin, three to five grains, three times a day. Ice to the back of the neck will sometimes relieve the discomfort in the head better than when applied to the head directly.

Most cases of chronic cerebral hyperæmia are also complicated with nervous exhaustion, and it may be desirable to give tonics to counteract the exhaustion. The vaso-motor nervous system is at fault, and requires not only a temporary stimulant to cause the arteries to contract, but it needs also to be permanently strengthened. A systematic course of hydrotherapy may be of value in this direction; also the ordinary tonics.

The chief object of these remedies is to restore the normal action of the arteries and the vaso-motor nerves. To do this, iron, strychnia, arsenic, quinine, zinc, nutritious but unstimulating food, are the most valuable agents. Spirituous liquors are to be avoided; tea and coffee taken only in moderation, if at all; tobacco should be forbidden. It is scarcely necessary to mention that the digestive and other functions should be kept in a normal condition.

Those who have had attacks, or who seem liable to attacks of cerebral congestion, should avoid public gatherings, where the air is liable to become impure and heated, and where there is more or less excitement, as theatres, concerts, balls, etc. They should be quiet in all their movements, avoiding exertions which would cause an increase of blood-pressure in the brain, as running, lifting weights, straining at stool, and venereal indulgence. They should sleep in cool, well-ventilated rooms; better on a hair mattress, with head elevated. They should take exercise in the open air, but avoid being chilled in cold weather. All intellectual efforts which produce the least discomfort in the head should be avoided. As one cannot stay at home surrounded by familiar objects, without the mind running more or less in its old ruts, and being recalled by old associations into old trains of thought, it is especially important to break up all such associations in cases of chronic hyperæmia, and, where the patient's health permits, travelling or a sojourn away from home is very desirable. Often it is the method whereby quickest relief can be obtained.

— A penetrating pistol shot wound of the abdomen, successfully treated by laparotomy and suture of the intestines, is reported by Dr. John B. Hamilton, Supervising Surgeon General of the Marine Hospital Service, in the *Journal of the American Medical Association*. Eleven wounds requiring suture were found in the small intestine and two in the ascending colon.

### SUCCESSFUL CASE OF LAPAROTOMY FOR INTESTINAL OBSTRUCTION.

BY JOSEPH B. REARD, M.D., WESTFORD, MASS.

On Tuesday evening, July 21st, 1885, J. H., aged twenty-five, farmer, of Irish parentage, a man of excellent habits, came to my office with the following history: On the Saturday previous he had fallen from a load of hay, catching one foot in the reins as he fell, and striking the ground on his hands. By considerable muscular effort he raised himself and freed his foot. He had no pain directly following the accident, and attended a ball, dancing ten or twelve times in the evening. Sunday he was conscious of not feeling quite as well as usual, but there was nothing distinctive, and he attributed his feelings to the wrench received in his fall. His bowels moved so slightly Sunday, that he took a tablespoonful of Epsom Salts, thinking to relieve the feeling of distress and uneasiness in the abdomen. Monday the cathartic had not moved the bowels, and he repeated the dose. The pain and distress were very severe during the forenoon; but about noon he became easier, and worked in the hayfield some in the afternoon. In the morning he passed a small amount of feces with considerable effort and straining. Tuesday the pain was worse again, and in the afternoon he vomited three or four times. Monday and Tuesday he had no appetite for food, but took small quantities of gruel, milk, toast, and eggs. He referred his pain to the hypogastric region, three inches to the right of the median line, and two and a half inches below the umbilicus. Its area was not more than two inches in diameter. I gave him three comp. cath. pills, and directed him to repeat the dose in six or eight hours if needed, and also gave him some morphine pills one-eighth grain, to be used every four hours if in pain.

Wednesday morning at four o'clock, I was called to see him. As he had slept fairly well until midnight, and the pain was not severe, he had not used any of the morphine, but had taken three more comp. cath. pills at one o'clock. Had tried repeatedly to get an evacuation of the bowels, there being a continual desire to strain and force a passage. About two o'clock, the vomiting returned, and until I saw him at four o'clock he had vomited every fifteen or twenty minutes. There was severe pain in the spot above referred to, and I found marked tenderness on pressure at that point. Could discover no tumor. The abdomen was considerably distended by gas, but not tender to pressure; he had passed no gas from the bowels, nor had they responded to the cathartic pills. From the history of the case, the steady localization of the pain, and its limited area, I decided upon intestinal obstruction from some cause. I then gave hypodermically morph. sulph. 1-1 grain, atrop. sulph. 1-50 grain, and tried large enemata of warm water, but with no effect; the water was passed with no discoloration from feces. I kept the patient for the next twenty-four hours thoroughly under the influence of morphine and atropia, 1-8 grain of former and 1-200 grain of the latter every four to six hours as needed. Wednesday evening, he having been ten hours without voiding urine, I used the catheter, and was obliged to resort to it every eight or ten hours for the following five days.

Thursday a.m. Patient looking badly, eyes sunken, countenance anxious, breathing thoracic, body covered

with cold sweat, bowels not moved, and no escape of gas, stomach unable to retain anything whatever, pain and tenderness in the spot already mentioned still present, and tenderness over a somewhat increased area three or four inches in diameter, temperature  $98^{\circ}$  pulse 110-120. The patient echoed my own conviction when he said "Doctor, I can't stand it much longer." I explained to him and his family my opinion of the case, that he had occlusion of the bowels, that from appearances the end seemed near, and I suggested an operation as his only chance of recovery. They consented, and I immediately called Dr. John C. Irish, of Lowell, who concurred in my diagnosis, and at noon on Thursday the 24th, he performed laparotomy in the presence of Drs. Bradt and Hoar of Lowell, and myself.

The patient being under ether the abdomen was opened in the median line by an incision seven inches long, reaching from the umbilicus to the pubes. Owing to the tense condition of the recti muscles, the incision was extended an inch above the umbilicus, and the left rectus muscle was divided at the left of the umbilicus.

We could learn nothing from inspection with the bowels *in situ*, on account of the extreme distension of the intestines from accumulated gas; nor could anything be ascertained by sense of touch with the hand in the abdominal cavity. Therefore the intestines were rapidly but carefully drawn out until about fifteen feet of them lay upon the abdomen, when sharp resistance was felt and the increased congestion of the intestines showed the constriction was reached. Dr. Irish then passed his hand into the abdominal cavity and withdrew the invaginated portion and relieved the obstruction.

At the location of the intussusception, which was ileo-caecal, the bowel was intensely congested and somewhat darkened in hue. The invaginated portion, about three inches in length, was thickly studded with deposits of lymph. The congestion extended up the ileum only a few inches above the obstruction. The remainder of the small intestine appeared to be free from any inflammatory action. It was, however, greatly distended with gas, and in the lower portion of the ileum near the site of the invagination the distension had become very great. The colon was free from congestion and flaccid.

Up to this time the bowels outside the abdomen had lain perfectly quiet and dormant; but when the constriction was relieved, there was a sudden rush of gas and the peristaltic action of the intestines started up, and gas escaped from the anus together with a large, thin, feculent, discharge. The intestines were replaced with comparative ease, and the incision closed with silk sutures and adhesive straps. There was profound shock during the manipulation of the bowels, though the time of exposure was not more than five minutes. Our hands were washed in a five per cent solution of carbolic acid, and the instruments and sponges were immersed in a solution of the same strength.

Patient rallied well and quickly from the operation, and was given a hypodermic injection of morphine, one sixth grain every five or six hours for three days, and rectal injections of three ounces milk and half ounce brandy, every three hours. Gas was passed freely, and the bowels moved spontaneously on the fourth day. Temperature on evening of third day was  $101^{\circ}$ , at no other time did it rise above  $100^{\circ}$ . After the third day the injections of milk and brandy were discontinued and he was fed by the mouth, with milk, beet-tea, custards, and eggs. The wound healed

throughout by primary union. Stitches were removed on eighth and ninth days, and patient sat up on fourteenth day.

In this case the following points are of interest:—

(1) The persistent and localized pain at the seat of obstruction, and the absence of any tumor at that point.

(2) The length of the incision. Some authors advise an incision only two or three inches in length. When we consider that shock is the most formidable factor in these cases, and that it begins the moment the manipulations of the bowel commence, and continues until the intestines are replaced, it seems to me that the long incision is far preferable to a short one. With the former you have the additional room to work in, and the reposition of bowels is much more easily effected.

(3) The agitation and peristaltic action of the intestines as they lay upon the abdomen, and the evacuation of the bowels and escape of gas immediately following the relief of the constriction.

I am indebted to Dr. Irish for the following summary of cases reported, where the operation was deliberately undertaken for occlusion of the bowels by invagination, volvulus, or constricting bands:—

Whole number of cases . . . . .	17
Adults . . . . .	10
Deaths . . . . .	6
Recoveries . . . . .	4
Children . . . . .	5
Deaths . . . . .	2
Recoveries . . . . .	3

Two cases not stated whether adults or children — deaths.

This table would indicate that the operation is more favorable in children than adults, probably from the fact that the obstruction in children is more likely to be of a very acute character, is more promptly diagnosed, and the operation made in a short time after very grave symptoms have declared themselves. The detailed reports of several of the above cases of adults, show that the operation was deferred until it was indeed an operation of last resort of very desperate character.

Recoveries are distributed geographically, as follows:—

Adults — France 1, England 2, Scotland 1.

Children — America 1, England 2.

Cause of death, in five cases, shock, a few hours after the operation.

The above summary is as complete as the resources within our reach allowed us to make. It would appear from this that the case I have described is the first successful case of laparotomy for intestinal obstruction in an adult, that has been reported in this country.

#### TREATMENT OF ABORTION, WITH CASES.<sup>1</sup>

BY J. L. SULLIVAN, M.D., OF MALDEN.

THE proper treatment of abortion, or, strictly speaking, of some of the conditions which attend abortion, is still an open question. That the existing antagonism of opinion and method is fostered by no dearth of interest in the subject, or of ability enlisted in its discussions, a glance at current medical literature will confirm. Nor is the disagreement occasioned by any scarcity of clinical opportunities. We live in a period of prevailing feticide.

<sup>1</sup> Read at the Obstetrical Section of the Suffolk District Medical Society, March 18, 1885.

Rather is it due, I believe, to the unavoidable circumstance that the field of obstetric practice in this direction is broad and stretches beyond the horizon of individual experience. *Ars longa, vita brevis.*

According to recent estimates the proportion of abortions and miscarriages to deliveries at term is not less than one to three; in other words, of all impregnated ova in the human female at least twenty-five per cent perish in immaturity, compelling, on the part of the woman concerned, no small sacrifice of health and sometimes of life.

Where interests of such magnitude and importance are involved, the settlement of any doubtful or controverted point is a desideratum, and any observations which tend to this result will be regarded, I trust, as not unworthy of attention.

In the condition known as incomplete abortion, three distinct methods of treatment have been adopted:—

(1) *The radical method*, championed by distinguished obstetricians, that is, the immediate evacuation of the contents of the uterine cavity.

(2) *The expectant method*, pursued by perhaps the majority of physicians, that is, the plan of patient waiting for nature to effect the expulsion of the product of conception, the physician interfering only when the patient's life or health is threatened, or when the natural powers seem inadequate to their task.

(3) *Nihilism*, or the let-alone, or do-absolutely-nothing plan, which differs from the expectant method in this, it forbears to invade the uterine cavity. The physician, who chooses this method, while combating symptoms as they arise, so far leaves the case to itself, that he relies for the extrusion of the ovum or decidua on the unassisted powers of the female economy. Probably few physicians take this course to-day, but the list would include some able men.

It is of the last, or let-alone plan, that I shall speak to-night.

How widely a belief in absolute non-interference with the cavity of the aborting uterus prevails amongst physicians in this State, and how consistently in the emergencies of actual practice the plan is carried out by those who advocate it on theoretical grounds, I have no means of determining. I presume, however, that during the period which preceded the discovery of anaesthesia, the birth of modern gynaecology and the use of antiseptics, the let-alone method was much more frequently employed than it now is. That it is no mere relic of fossilized conservatism, or, if you please, no mere fragment of adipocere from some long defunct corpus medicum, will appear from the fact that only two years ago my attention was strongly directed to the subject in consequence of a statement made by a distinguished Fellow of this Society at one of its District Meetings, where the treatment of abortion and miscarriage formed the topic of discussion. The gentleman to whom I refer, said that on reviewing his forty years' experience in midwifery he could recall no case of incomplete abortion, or of premature labor, which had required any operative procedure for the delivery of the secundines, etc. Retention of a dead ovum or a portion of placenta had occurred as frequently in his practice as in that of his neighbors, and for the evacuation of the contents of the womb he had uniformly relied upon the unaided efforts of nature, and his patients had invariably recovered. This testimony to the triumph of the conservative principle in the management of these cases, emanating, as it did,

from an experienced and thoroughly trustworthy source, struck me as entitled to serious consideration, and I asked myself the question, how shall we interpret the extraordinary success of this method, exemplified, as it is, not in the favorable termination of a single critical case, but in an unbroken series of cases extending through many years. Shall we regard this result as an instance of unparalleled good fortune, or as an expression of an important truth not hitherto fully recognized, that aborting women, so far as the extrusion of the uterine contents is concerned, if left to the kindly offices of nature, do well. Ought not this protracted experience to serve as a lesson and a rebuke to those amongst us whose treatment in similar cases is more or less heroic?

Finding myself unable to answer this inquiry from any data at my command, I resolved to test the let-alone treatment of incomplete abortion in my own practice, as far as this could be done without compromising the health or lives of the patients. What follows, then, is the record of a conscientious effort to determine the practical value, or otherwise, in certain critical obstetric conditions, of the *vis medicatrix naturæ*. Six aborting women became, in turn, the unwitting subjects of this quasi-therapeutical experiment, which ended with the sixth case, my object being then accomplished. The interest lent these cases not otherwise remarkable in themselves (with perhaps one exception) by the special investigations to which they were made to contribute, is my apology for asking the attention of the Section to the salient points of each.

CASE I. Mrs. S., aged forty-two years, American, multipara, aborted for the third time October 13, 1883, being then three months and a half advanced in her seventh pregnancy. On my arrival I found the fetus already expelled, the placenta retained and partially attached, the closed condition of the os and cervix uteri precluding the possibility of its extraction without the previous use of tents. The woman was steadily losing blood in quantity not immediately alarming but too profuse to go on unchecked. I therefore plugged the os and tamponed the vagina thoroughly, à la Simpson, with strips of cotton cloth. The plug and tampon remained in situ twenty-four hours and were then replaced by others which were left for the same length of time. Meanwhile considerable sero-sanguineous discharge oozed through the cloth and the patient grew sensibly weaker. Failing in a third and last attempt to fully control the bleeding by means of the tampon, I yielded to the patient's entreaties, dilated the cervix with sponge tents, and extracted the contents of the uterus, under ether. Mrs. S. made a good though tedious recovery, the debility and anaemia consequent on the abortion, and aggravated, perhaps, by delay in resorting to radical treatment, persisted for several months.

CASE II. Mrs. M., American, aged twenty-four years, a perfectly healthy married woman in good circumstances, when four and one-half months pregnant with her second child, was taken January 2, 1884, with slight flowing, unattended with pain. On discovering her situation the lady sent for me. On my arrival she was ordered to take the bed. The usual measures for the prevention of abortion were tried but proved unavailing. Four days later travail pains began, and she soon gave birth to the fetus. Thereupon the womb contracted firmly on the undetached placenta and all haemorrhage ceased. No ergot was given.

During the succeeding four days the situation continued unchanged. There was no pain and absolutely no vaginal discharge. Her napkins were removed unsoiled and no trace of blood appeared on the examining finger. Meanwhile the umbilical cord separated from its placental attachment and came away but the womb remained closed. The morning of the fifth day was ushered in with pains, which caused the womb to dilate. The afterbirth could now be felt, lying high up and firmly attached — throughout its whole extent — to the uterine wall. A slight sanguineous discharge, less than occurs in scanty menstruation, now set in. Five days afterwards, the *status quo* continuing, and the lady's husband refusing to sanction any further dalliance with the case, I etherized the patient and with some difficulty removed the still firmly adherent placenta. No unpleasant symptoms followed, and Mrs. M. rapidly regained her usual excellent health.

CASE III. Mrs. W., aged thirty years, multipara, a healthy, hard-worked American female, wife of a respectable and well-to-do mechanic, determined to cut short her third pregnancy. By means unknown to the writer the ovum perished at two and a half months. Notwithstanding a constant, fetid vaginal discharge, Mrs. W. attended to her household duties and exercised more than usual out of doors. When this state of affairs had lasted a fortnight a sudden rush of blood from the vagina caused Mrs. W. to fall swooning on the kitchen floor. On reaching the spot on the evening of August 3, 1884, I found the woman in a condition of partial unconsciousness and well-nigh fatal exhaustion. A pool of coagulating blood marked the place where she had fallen; the bed to which she had been conveyed was swimming in blood, blood was still streaming from the vulva as fast as the failing circulation would allow. Not a moment was to be lost. Baring my arm and hastily thrusting it into the vagina, which was relaxed, I succeeded in removing a putrid mass from the cavity of the womb, when fortunately for both patient and physician the flaccid organ contracted and the bleeding ceased. Mrs. W. slowly rallied, but she is still feeble and an anemic to a sad degree. The value of this experiment is not lessened by the fact that it was tried by the patient herself.

CASE IV. Mrs. E., multipara, aged thirty-two years, a healthy, hard-working Irish woman, four and one half months advanced in her fifth pregnancy, aborted for the second time on the morning of September 9, 1884. I was not present at the delivery, but the attending physician on leaving the house, to use the patient's words, pronounced her "all right." There were several bystanders, none of whom had seen the afterbirth, and I was sent for to ascertain if the delivery had been completed. Examination disclosed a state of tetanic uterine contraction, and I learned that ergot had been given. Feeling confident that the cavity of the enlarged and globular womb contained a portion of the product of conception, I enjoined absolute rest in bed, and explained to the patient the necessity of obedience. A week later Mrs. E. was assailed with sudden and copious flooding, which ceased only on her becoming faint. On four succeeding occasions, at intervals of several days the bleeding returned. The patient daily grew weaker, and presented a striking picture of progressive anemia. Convinced of the uselessness, if not wickedness, of

longer delay, I dilated the still strongly contracted cervix with several successive tents, and October 12, 1884, removed from the left corner of the womb a portion of placenta. A sharp attack of metro-peritonitis, ushered in by rigors, high temperature and rapid pulse kept the patient's life in jeopardy for several weeks. Her health is still poor.

CASE V. Mrs. K., a young, newly-married American girl, wife of a well-to-do mechanic, for the first time pregnant, succeeded in causing the death of the ovum at two and a half months. I saw her April 4, 1884; she was about doing house work, but complained of feeling ill, and of an offensive vaginal discharge. Ascertaining that the womb contained a putrescent ovum, and that the cervix was elongated and brawny, I sent the patient to bed where she remained for two weeks without any marked change in the symptoms. A severe chill followed by abdominal tenderness and fever caused her to summon me for the second visit on the 18th. Dilatation of the cervix by a succession of tents was finally accomplished, and the uterine contents extracted on the 25th. A long and severe attack of pelvic-peritonitis, from which Mrs. K. has not yet fully recovered, completes the outline of the case.

CASE VI. Miss A., aged twenty-two, American, unmarried, a mill-operative, with whose previous history I am unacquainted, began to menstruate as usual on September 20, 1884. On the 9th of October she had sexual intercourse. The catamenia due October 18th, failing to appear, she consulted a doctor, who prescribed some pills, but according to her account, did nothing more. November 19th she was taken with pains and flowing, and passed per vaginam several small coagula and fragments of a mutilated ovum, which were preserved for my inspection. On the next day I was sent for and found her in bed, free from pains and flowing, womb enlarged, os slightly patulous and soft. Enjoining rest in bed until abortion terminated, and giving suitable directions concerning diet, etc., I left with the understanding that I was to be sent for when any new symptoms appeared. The subsequent history is as follows: patient kept her bed one week, then wearying of the confinement and feeling quite well, she got up, went about the house and ventured out of doors for several short walks. Thursday, December 18th, having decided to go "down East" next day, she spent several hours in packing her trunk. Just as the work was finished she was seized with excruciating pains in the hypogastrium, became collapsed and died within an hour. She was breathing her last when I reached the bedside. No autopsy was permitted, but a careful examination of the abdomen and pelvic cavity by conjoined manipulations satisfied me that death had been caused by internal hemorrhage. Not a drop of blood escaped from the os uteri. With the fatal termination of this case I abandoned the conservative treatment of incomplete abortion.

The foregoing history leads to the conclusion that an early resort to radical measures was indicated in each case and might possibly have saved a life.

The contrast between the outcome of these abortions and the success achieved by our colleague emphasizes again the familiar, but ever instructive lesson, namely: Of the great circle of collective medical experience how small an arc is that which the practice of any one man subtends!

## REPORT ON OBSTETRICS.

BY C. M. GREEN, M.D.

## THE RELATIVE WEIGHTS OF NEWBORN CHILDREN.

Wolff,<sup>1</sup> in his inaugural dissertation, Munich, 1883, has given the results of his industrious examination of the statistics of the Lying-in Hospital in Basel with reference to the relative weights of newborn infants. His inquiry covers the period from 1873 to 1882 inclusive, and embraces the statistics of 2,032 children. The analysis of his numerous tables leads him to the following conclusions:—

(1) Full-term children, the offspring of multiparæ, and boys weigh more at birth than the prematurely born, the offspring of primiparæ, and girls. The difference between the weights of infants of primiparæ and multiparæ is less when the children are prematurely born.

(2) The majority of infants lose weight in the first hours of life: in nine per cent, however, there is a gain in weight.

(3) The loss in weight of children of both sexes ends in the first three days. Infants of multiparæ and full-term children complete their loss more quickly, in the average, than the newborn of primiparæ and premature infants.

(4) The normal amount of loss in weight reaches from 3.5 to 11.5 ounces; sex and development of the children are without influence.

(5) In the same given period of time, a greater number of boys re-attain their initial weight than girls, and boys of multiparæ in greater numbers than those of primiparæ.

(6) At the end of seven days half of all newborn infants have re-attained their initial weight, and it is to be considered an exception for an infant to be below its initial weight after the fifteenth day.

(7) More boys and children of multiparæ re-attain their initial weight in the first week than do girls and children of primiparæ.

(8) During the usual stay in hospital more boys than girls show an increase over their initial weight, especially so the children of multiparæ and those fully developed.

(9) The usual daily increase in weight amounts to 0.35 ounce. Full-term children, boys, and infants of multiparæ make relatively larger daily gains.

## THE DIAGNOSTIC VALUE OF THE FETAL HEART-BEATS.

Boltoni,<sup>2</sup> of the University of Padua, has made a careful clinical study of this subject, and come to the conclusion that the number of heart-beats is a more constant guide to the development than to the sex of the child. A record was kept of the fetal heart-beats in all cases admitted to the obstetric clinic in 1883-4. The count being made three times in each case, always at the same hour, and an average of the three counts was taken. At the birth of the child its sex, weight, length and bi-parietal diameter were carefully noted and compared with the previously determined heart-beats. In drawing his conclusions Boltoni selected one hundred women, whose labor had been normal and in whom the fetal heart had been counted between the eighth and ninth solar months. He found that the number of

heart-beats bears no necessary relation to the sex of the child, but does bear a constant and proportional relation to the weight, length, and bi-parietal diameter, in other words, to the size of the body. The smaller number of heart-beats more frequently corresponds to the male sex only because boys, as a rule, weigh more than girls at birth. The two most frequent rates observed were 128 and 144: with the first rate, more boys than girls corresponded, and with the second, more girls than boys. With 128 heart-beats the weight of the child, whether boy or girl, was over 6.4 pounds: with 144, the weight was always less than this.

## HYDROCHLORATE OF COCAINE IN THE VOMITING OF PREGNANCY.

Weiss,<sup>3</sup> of Prague, has used this remedy successfully in a case of vomiting of pregnancy which had resisted all previous attempts at relief. The patient was weak and anæmic, of a nervous disposition, and had suffered in three previous pregnancies with persistent vomiting: in the present pregnancy her condition was serious. Weiss prescribed:

R. Hydrochlorate of Cocaine . . . . .	gr. ii.
Alcohol, enough to dissolve . . . . .	
Water . . . . .	℥ v.
S. One teaspoonful every half-hour. . . . .	

After the sixth dose three table-spoonfuls of milk were well borne: after the eighth, a cup of broth with egg, without vomiting. After the sixteenth dose the patient ate with relish chicken broth, slices of white chicken meat, and drank a glass of wine, without vomiting. The drug was then withdrawn for a time, owing to an increased frequency of pulse and respiration; but hourly doses were subsequently given with the result of entirely checking the vomiting and enabling the patient to regain her former strength.

## PUERPERAL ECLAMPSIA.

In concluding an interesting paper<sup>4</sup> on this subject, Dr. Robert A. Murray considers two very important questions, namely, whether pregnancy causes Bright's disease, and whether we are warranted in advising that a future pregnancy will be safe and successful in its issue when the patient has once suffered with eclampsia. From his examination of the statistics of the Registrar-General, and supported by the opinions of Roberts and Dickinson, Dr. Murray concludes that there can be no doubt that the puerperal state is a prolific cause of Bright's disease.

Regarding the second question, the author has seen a good many cases of persistent albuminuria with characteristic symptoms, which had begun in a first, and had become intensified in succeeding, pregnancies. From his clinical experience, therefore, the author concludes:

"(1) That subsequent pregnancies in patients who have had convulsions are to be avoided for a long period, so that the kidneys may have their functions completely restored."

"(2) That on the occurrence of pregnancy, the urine should be frequently examined, and an endeavor made by prophylaxis to guard against the uræmic condition."

"(3) That abortion, or premature labor, should be promptly induced, when uræmic symptoms present, when in previous pregnancies severe eclampsia has occurred."

THE INFLUENCE ON SECOND LABORS OF THE LENGTH OF INTERVAL SINCE THE FIRST LABOR.

It is well known that a woman pregnant for the second time, when a long interval has passed since her first pregnancy, approaches her labor with greater anxiety, both for herself and her offspring, than the secundigravida whose first labor has occurred within a few years. It is also known, that if the first labor has left behind no considerable injuries, the marks of it can sometimes so far disappear and the cervix, after a long interval, so far regain its original appearance that it is often scarcely possible to tell, in the absence of a definite history, whether a given patient is a primigravida, or whether she has given birth to a child some years previously. These two facts give rise to the conjecture that a second labor after a long interval may differ materially from ordinary second labors, and may perhaps resemble first labors. Since no attempt has hitherto been made to determine whether or not this conjecture is well grounded, Kleinwächter<sup>5</sup> has set himself to find out whether, and in what way, long intervals between the first and second pregnancies exercise an influence on the second gestation, the second labor, and the second puerperium.

The material on which the author based his observations embraced 397 secundigravida, of which number 395 gave birth: of this number, 94 bore their second child after an interval of from six to sixteen years. From the tabulated statistics of these 395 cases, Kleinwächter has made the following interesting deductions:

(1) Secundigravida, with a long interval (six to sixteen years) since their first pregnancy, suffer during gestation both with accidental complications and with those dependent on the pregnant state much more frequently than those pregnant for a second time after a short interval (one to five years). The reverse appears to be the case with ante-partum hemorrhages.

(2) A relative and absolute increase in the amount of liquor amnii is observed after a long interval much more frequently than after a short one: especially is this true after an interval of ten years or more.

(3) The duration of second labors in general is in the average about 10.5 hours, and the relative length of the several stages to one another is about the same as with multiparae generally. But secundiparae after a long interval have a longer first stage than after a short interval, the other two stages remaining about the same. If, however, the interval is ten years or more, all three stages are considerably lengthened, and the labor lasts about as long as that of primiparae: in fact, the third stage in such cases appears to be even longer than in first labors. In other words, after a long interval, the pains are more frequently weak and ineffectual than after a short interval.

(4) Operative interference with second labors after a long interval is necessary twice as often as after a short interval, and tears of the perineum occur more frequently. Adherent placenta and post-partum hemorrhage are more frequently observed after a long interval.

(5) Affections of the kidneys occur more frequently after long, than after short, intervals. Especially noticeable is the increased frequency of oedema of the lower extremities without albuminuria, particularly after an interval of ten years or more.

(6) The likelihood of mastitis diminishes with the length of the interval: so also does the probability that the mother will be able to suckle.

(7) The morbidity and mortality per cent of puerperal disease rises considerably with the increase of interval, and is especially high after an interval of ten years or more. There appears, however, to be no inclination to puerperal mania after a long interval.

(8) The longer the interval, the more frequent the premature, spontaneous interruption of the pregnancy, especially when the interval is ten years or more. The probability of twin pregnancy increases with the length of interval, and so does the frequency of the birth of monstrosities.

(9) The relative number of girls born of secundiparae increases progressively with the length of interval; and the longer the interval, the heavier and longer is the infant.

(10) With the increase of interval there is a progressively increasing mortality of children,—the loss of fetal life embracing not only the stillborn, but those who die within the first eight days.

In other words, it may be stated that with an increase of interval between the first and second labors, the second pregnancy will be more frequently attended with sickness and the ailments incidental to that condition, and premature labor will more frequently occur; the labor will be longer; instrumental interference will therefore be more frequently necessary, the perineum will oftener be torn, hemorrhage will more frequently follow, and the puerpera will more frequently sicken and die. Further, the longer the interval, the more frequently will twins be born, the greater will be the fetal weight and length, and the greater will be the number of stillborn children and of those who perish within the first eight days. On the other hand, with an increased interval is a decreased frequency of ante-partum hemorrhage and of marked diminution in the amount of liquor amnii; a diminished functional activity of the mammary glands, a diminished tendency to puerperal mania, and finally a decreased number of male offspring.

If these conclusions are compared with a previous article of Kleinwächter's on *The Influence of Age on the Labor of Primiparae*,<sup>6</sup> it will be seen that with few exceptions, of secondary importance, the secundigravida with an interval of ten years or more finds herself under about the same relatively unfavorable circumstances as the old primipara; and the explanation of this fact, according to the author, is to be found in the increased age of the former: that is, that the consequences and influences of the first labor may disappear after a long period of years, and that the woman who then becomes pregnant for a second time is virtually an old primipara.

— It has been proposed to establish a temperance hospital in Melbourne in which patients may be treated "without the use of alcohol except as a drug." The *Australasian Medical Gazette* in editorial comments on the proposed hospital, expresses the opinion that all patients are in a better position to be cured when under the care of practitioners having no strongly marked prejudices either for or against alcohol, than in a hospital the very principle of whose existence is a prejudice of its officers against a valuable, though often abused means of cure.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT E. DIXON, M.D., SECRETARY.

MARCH 18, 1885. The meeting was called to order at 7.45 o'clock. Dr. J. R. CHADWICK in the chair. fifty-two members being present.

Dr. JOHN L. SULLIVAN, of Malden, read a paper entitled

#### TREATMENT OF ABORTION, WITH CASES.<sup>1</sup>

Dr. SINCLAIR said that his plan of treatment, when called to a woman aborting previous to the fourth month, was to arrest the hemorrhage if present to any extent. The percentage of cases of abortion, once started up, that are checked, is extremely small. Dr. Sinclair always examines the woman to learn the condition of the os uteri, whether patulous or not. If the cervix is dilating he gives opium to stop it. He has used the fluid extract of viburnum, but not with good results. If the pain is allayed by opium, good results may be obtained; but generally the miscarriage is not checked. If there is much hemorrhage, the vagina should be tamponed thoroughly, packing firmly from the cul-de-sac downward. The tampon induces pain, and, if removed in twelve hours, in all probability the fetus will be found upon it. Sometimes it is necessary to tampon again and again.

Another and a troublesome class of cases is that in which the fetus comes away, the os closing behind it. The secundines left in the uterus will come away, unless they are adherent. When they do come, however, they are sure to be accompanied by hemorrhage. If the uterine contents are within reach, they should be removed at once. This is best accomplished by pressure upon the fundus uteri with the left hand, and the insertion of the right forefinger into the uterus. Unless the uterine contents are low down, Dr. Sinclair believes in letting them alone. One bad result from a piece of decidua being left in the uterus is that the woman is likely to bleed a great deal and may become moribund. A very small piece of secundines thus retained may be the cause of death, as in a case referred to.

Dr. MINOT remarked that the chances of arresting the process of abortion, after it has once begun, are small. Abortion, however, can sometimes be prevented in patients who have previously been unable to carry a fetus to term. In his own experience this has several times been accomplished by placing a small soft rubber ring pessary in the vagina, the upper part lying behind the cervix, which seems to serve as an elastic support to the uterus, shielding it from sudden movements, etc., on the part of the patient, — a great improvement on the old method of keeping the patient in bed for several months. The treatment of abortion is simple. If there be much hemorrhage, this should be arrested by the tampon until the ovum be expelled. It sometimes happens that a considerable mass of placenta remains behind, which may be retained for an indefinite length of time, giving rise to often-recurrent hemorrhage. It should therefore be artificially removed after a reasonable delay, if the womb seems unable to expel it. The patient should be etherized and placed on her left side, close to the edge of the bed, with the

knees well drawn up. The operator introduces his right hand into the vagina, the forefinger entering the womb. The fundus of the latter being steadied, and, if necessary, depressed by the left hand applied above the pubes, externally, the interior of the uterus can be easily and safely explored, and anything adhering to its walls removed. He had never met with a case in which it was necessary to dilate the os or canal of the cervix. Of course, the operation should be done with antiseptic precautions.

Dr. FIFIELD stated that it is very rare that a physician is called to prevent an abortion, and often would not be allowed to do so, if he proposed it. It is sometimes possible to check or delay an abortion already started, and the woman may even go on carrying some part of the ovum to full term. Dr. Sullivan's experience in the use of sponge tents is strong testimony of the fact by him stated, namely, that any physician's experience subtends a small area of the truth. Dr. Fifield believes largely in the expectant treatment, and with him it has been rare that he has had to remove the secundines. If it becomes necessary to empty the uterus, the uterine scoop, invented by Dr. Benjamin Cushing, of Dorchester, fulfils every indication. Dr. Miller, of Dorchester, used to pass a gum elastic catheter, with the stilette removed, into the uterus and leave it there, when there were any remains of an abortion present, and generally got expulsion of the contents. In the very early months, vaginal injections of hot water are best. In the later, the catheter does well. Hemorrhage after the supposed expulsion of the ovum does not always indicate that secundines are left in the uterus. Hemorrhage may occur without such contents being present. He had a case of this kind, where the hemorrhage continued for some time. He dilated the cervix and explored the uterus, but found nothing. He applied diluted tincture of iodine to the interior of the uterus with complete success; but septicæmia followed the use of the sponge tents. He had had bad results from the use of the latter. He believes firmly in the expectant treatment. He urged that a sponge-tent should not remain *in situ* more than twelve hours, and he strongly deprecated the *repeated* use of tents. One may be perhaps safely used; but two or three are infinitely dangerous.

Dr. BOARDMAN said that the scope of this paper appeared to limit the discussion to the treatment of an abortion, which has become inevitable. In such cases it was his custom to follow both the expectant method and the radical one of an immediate, forcible removal of the contents of the uterus. Ordinarily nature carries the patient through, with the complete and safe removal of the products of conception; and his practice is to wait a reasonable time, in order to allow nature to accomplish her work; in the mean time, however, keeping a close watch over the patient with a view of meeting important symptoms as they arise, and among these, the most usual and important is hemorrhage. For the arrest of this he does not believe in the old method of tamponing the vagina, but in plugging the cervix with the finger. By this method we obtain all the benefits, including the arrest of hemorrhage and the promotion of the expulsion of the fetus, while the finger is insinuated within the cervical canal, after the manner so ably defended in certain cases by Dr. Sinclair. Then, with the finger or fingers, and the various forceps and curettes now at our disposal, it is an easy, expeditious and safe method to

<sup>1</sup> See page 222.

empty the uterus. He contended that, *when the abortion is inevitable*, it is not such a difficult matter as many assert to obtain entrance for the finger or curette into the uterus, especially when hæmorrhage is going on. He had found that wherever there is abnormal hæmorrhage, it is always an easy matter to introduce say, a Thomas' curette, even into a multiparous uterus. In private, and especially in hospital practice, he was repeatedly consulted by patients suffering with the ills incident to the retention of some remains of an abortion, which occurred weeks and months before, and where the purely expectant, or rather, the do-nothing method had been followed.

In a few words he would advise a thorough examination of each case, and not to place any confidence in the statement of friends or bystanders, or indeed of many physicians, as to what has already escaped from the uterus; that having satisfied ourselves that the uterus contains a fetus, and that abortion is unavoidable, we should wait perhaps a few days for nature to complete her work, and then or before, if urgent symptoms arise, we are under obligations to empty the uterus completely and as expeditiously as possible, consistent of course, with safety to the mother from unwarrantable violence.

Dr. ADAMS said the question wanting solution was, "shall we, in every case of incomplete abortion, proceed at once to dilate and remove the uterine contents?" Is it more dangerous to leave the case to Nature than to interfere? If statistical evidence were at hand, it might help us to solve this difficult question. Kastner has collated 429 cases of early forcible removal of the placenta with 69 deaths; that is, about 16 per cent. But such figures are fallacious.

If active interference is called for by frequent small hæmorrhages, which threaten septicæmia occurring at the end of two or three weeks, we must then proceed to empty the womb; but if the os uteri has closed, and there is neither hæmorrhage nor pain, or other symptoms, we had better wait. The evidence of writers on the subject seemed to show that the danger of sudden fatal hæmorrhage in abortion was not great, while the danger of septic infection was the greatest of all.

Shall we then dilate and forcibly remove the contents of the uterus in every case of incomplete abortion? The answer to this should be, "no." Dr. Adams cited a case where an abortion occurred at 3 months, the secundines not coming away until the following day; and 4 months after, the woman gave birth to a 7 months' child, which is now living.

The condition is probably more or less pathological in abortion. There may exist cancer or other disease, especially fibroids of the uterus; or the more frequent case of wounds or injuries caused by criminal interference and forcible dilation, scraping, scratching, or other efforts to clear out the womb, may do more harm than good. In fact, we are working in the dark.

No mention has been made of the method of preventing the "abortion habit," discovered by Sir James Y. Simpson. He would like to ask the experience of the gentlemen present in the use of chlorate of potash as a remedy. Dr. Adams had himself tried it in one case with a successful result.

Dr. REYNOLDS had in several instances used the remedy mentioned by Dr. Adams in large doses, 30 grains, three times daily, and had continued it for many months during the latter half of pregnancy; for example,

after failure in repeated pregnancies to go to full term after the birth of a putrid child or one imperfectly developed. In every instance he had expressly stated to the patient that he has no sufficient reason to promise good from the medicine; but he must admit that he has heard with surprise the conviction of its value which the families in question entertained. There is an impression among practitioners that large doses of chlorate of potash, long administered, risk the integrity of the structure of the kidney. On this account, the urine should be watched. The speaker had not been able to find evidence of such injury. If at his wit's end for means of treatment in cases like those mentioned, and if compelled to employ some remedy, he would again resort to chlorate of potash; but he can only offer conjecture as to its possible usefulness.

Dr. Reynolds, after rapidly reviewing the discussion of this question during the last five or six years, recalling the efforts of Dr. H. R. Storer and of Dr. Mathews Duncan to rouse attention to it more than twenty years ago, and mentioning the valuable paper lately read in Edinburgh by Dr. Angus McDonald, and the debate upon the subject in the New York Academy, said that to these widely accepted views as general statements of the character and results of the accident, and of the indications for treatment, little exception can be taken. Thus the dangers recounted: 1st, Exhaustion from loss of blood; 2d, Septicæmia; 3d, Morbid adherence of bits of the ovum and their subsequent polypoid growth; 4th, Subinvolution, and an unhealthy state of the membrane of the uterine cavity, may fairly be recognized as genuine. As to treatment, it is declared that the only satisfactory procedure is the immediate emptying of the uterus; that at least there ought to be no delay other than that required for a sufficient dilatation of the os.

The criminal character of do-nothing treatment in early abortion, is, on all hands, most emphatically laid down. It is, indeed, hardly possible, in view of the harm daily done to subsequent health, and not infrequently to life, by this brutal neglect, to use words strong enough in denouncing it.

But admitting this much, this manner of putting the treatment is far too absolute, and is, in fact, more than all other influences likely to bring about the very evils of which complaint is so justly made. Certain reservations must also surely be claimed before we accept as facts the foregoing enumeration of the dangers which the accident involves.

In hospitals and in dispensary districts, neglected cases undoubtedly present, at times, all these unhappy results. In hospitals, and in large centres, acquired skill and daily-renewed experience, make radical measures of treatment in early miscarriage, as a rule, both easy and safe. But in our time, nothing can so surely lead the average practitioner to do nothing in abortion as the dictum, that only emptying the uterus will serve the patient's purpose; to attempt that, he is either too unskilled or too timid. Again, whatever the truth in regard to miscarriage in general, the risk, in that proportion of cases occurring in private practice, in which from the onset, judicious care and watchful nursing are in force, merits quite a different description; especially is it necessary to strongly emphasize the great contrast in the frequency and the gravity of the several dangers. There is, in fact, for such cases, only a single risk worthy of notice; and in managing them, attention to that symptom dominates every other indication. In

a carefully-watched case, as in all others, no remedy is to be even named in comparison with the prompt and thorough removal of the ovum; but when for any reason that is not done, the one all-important step is, the preventing of any bleeding that can occasion even a beginning of exhaustion. It is seldom difficult under such conditions, to thoroughly stop any noteworthy loss of blood. The tendency to hemorrhage, if controlled from the outset, will very rarely indeed continue beyond thirty-six hours, provided there has been no unskilful meddling with the uterine contents. Such restraint of hemorrhage will, except in instances where the accident has occurred in the presence of extreme preëeding debility, reduce the possibility of septicæmia to about one thousandth of one per cent. As to the likelihood of imperfect uterine involution, wise care during the after-period will greatly tell on the result; and Nature will seldom, where there has been no bungling, keep in the cavity "placental arreste."

Dr. Angus McDonald loudly condemns the tampon. Dr. Macan congratulates himself, in an annual report, that in a considerable series of cases plugging has not once been done in his hospital. Plugging, with these writers, evidently means a long and tiresome process. In two minutes any medical man can introduce with the greatest ease one of the soft, pliable, India-rubber colpeurynters of French or American pattern, can inflate it, can in all but every instance, guarantee the patient against any appreciable farther bleeding. Not infrequently the distended bag, pressing the pelvic floor like a fetal head, sets up the desired uterine expulsive effort. Any attendant, nurse, sister, husband, of even moderate intelligence, may, with a little instruction, be taught to withdraw the appliance, to re-introduce it, to inflate it. For the do-nothing practitioner, this simple, inexpensive contrivance will bring wonderful, and yet utterly justifiable, peace of conscience, and it will prove itself to his patient of value inestimable.

A colpeurynter, when first fully inflated, causes pain; that soon gives place, with average women, to a mere sense of uncomfortable stretching. In rare instances, a slight opiate may be a wise addition to the treatment. It is essential that the bag be entered well past the inlet of the vagina. A badly retroflected uterus, containing a four months ovum, may make the use of this instrument impracticable. It may fail to be retained in a multipara whose vagina has been repeatedly stretched in often recurring births. A stiff, inflexible colpeurynter, like some of those seen in Vienna, is of little value.

#### NEW INSTRUMENTS.

Dr. ROBERT B. DIXON exhibited a head perforator for craniotomy, made of a trephine with its teeth completely covered by a movable bell-shaped cup to prevent injury to the vaginal soft parts during insertion. The trephine is connected with the handle by a spindle seven inches in length, around which is a spiral spring to regulate the pressure upon the cup. The advantages of this instrument are that it is considerably less expensive than other perforators; the pelvic curve in the instrument is avoided; it is very easily cleansed; having a small spindle allows plenty of room in the vagina for the operator's fingers; and it can be used with two hands, while those instruments which have a pelvic curve require three.

Dr. Dixon showed a decapitating hook, which he designed to obviate the difficulty of inserting, as in the old operation, two instruments, first the blunt hook to

break the neck, and then the cutting hook to sever the head from the body. This instrument is a conjunction of the blunt and sharp hooks. It is to be inserted into the vagina, and about the child's neck. Traction and a twist of the handle is sufficient to break the neck, then, without removing the instrument, but by turning a thumb-screw a concealed knife is drawn out one-fourth of an inch on the inner side of the blunt hook, and by traction, accompanied by a simple up and down movement of the handle, the point of the instrument being protected by the left fore-finger, the head is separated from the body.

Dr. DIXON also exhibited a douche tube, designed for use in vaginal injections. It is of hard rubber, and at its inner end, which is double the size of the spindle, are large lateral apertures through which the water can run in an abundant but slow current, which answers all the purposes of cleanliness. At the same time all danger of foetid material or air being forced into the uterus is avoided.

Dr. JAMES R. CHADWICK reported:—

#### TEN CASES OF PREGNANCY AND LABOR COMPLICATED WITH FIBROIDS.<sup>2</sup>

Dr. F. BERLIN reported the following case:—

Mrs. K., thirty-five years old, primipara, presented herself at the New England Hospital for women and children, Dec. 1st, 1884, wishing to be admitted to the maternity department. She stated that she always enjoyed good health; first menstruated at twelve years of age, always flowed regularly and moderately. She had been married a few months, and menstruated for the last time the 13th of May. In July she noticed she was getting larger, and discovered a tumor in the right hypochondrium. The first of October she first felt motion. When admitted to the Hospital, the uterus was found enlarged, as in an eight months pregnancy. At the upper right corner of the abdomen was a tumor the size of an orange. Lower down in the hypochondrium on this side was another tumor about the same size as the other one, but not as movable. On auscultation, foetal pulsations at the rate of 136 per minute could be distinctly heard to the left and below the umbilicus. An examination *per vaginam* revealed a mass above the brim of the pelvis, nearly filling out the whole inlet, and pushing the cervix uteri up close to the symphysis pubis. The mass was quite immovable, and an attempt to push it up, while the patient was in the knees-chest position, proved futile. It was decided to wait until the end of pregnancy, and she was sent home to return in January. She came back the 15th of January, no change having taken place in her condition, except that the tumor felt through the vagina had descended still lower, and the cervix uteri was barely within reach of the finger.

Dr. John Homan saw the case at the hospital at this time, and also thought it would be best to wait for nature to take its course. Owing to lack of room at the hospital, she was sent home, the 23d of January, with the understanding that at the slightest approach of pains she was to return to the hospital.

That very night she commenced to have pains, which, although at times of a very severe nature, she thought were nothing but colic. But they persisted the following day and evening, and she was brought to the hospital at 10.30 p.m., January 24th.

The pains were occurring every ten minutes. When

<sup>2</sup> See Journal of July 30, page 97.

examined, a perfect revolution of affairs seemed to have taken place. The lower tumor in the right side had entirely disappeared, and its place was occupied by the upper one. In the left side was a prominent mass which had not been felt before. Internally, the mass which had been felt the day previous had disappeared, and the lower segment of the uterus was found in its normal place. The cervix was soft, dilatable, and easily admitted the end of the index finger. A presenting part was felt, which gave the impression of being the breech. As the woman was very nervous and excited she was given a warm bath and ten grains of bromide of potash. The pains during the night gradually subsided, and she slept a good deal. The next day and the days following she was up and about, feeling perfectly well, having occasional slight pains.

February 5th, at 8 P.M., decided labor pains set in. Dr. Whitney, the resident physician, who watched and completed the labor, gives the following account:—

"During each of the pains the tumors grew harder and stood out more prominently, the one on the right side so much that it seemed as if it would burst through the abdominal walls. At 2 P.M., dilatation was complete, and at 2.30 A.M. the membranes ruptured and the right foot came down into the vagina. The woman seemed very much exhausted, pulse 120. After waiting half an hour and no progress being noticed, labor was assisted, and the body extracted up to the head, which latter was found extended and could not be brought down. After futile attempts to flex the head, forceps were put on and the head extracted. The child did not breathe; but the heart impulse was still felt. All efforts to resuscitate it proved in vain. There was no hemorrhage to speak of. The uterus contracted well, but remained large, reaching to the umbilicus. On its surface five separate tumors, varying from the size of an orange to that of a pigeon's egg, could be distinctly felt. The patient's convalescence went on uninterruptedly. She left the Hospital the 26th of February. The uterus was then three fingers' width below the umbilicus. Outlines of fundus of irregular shape, on its right side was a tumor the size of a large fist, freely movable and apparently connected with the uterus by a long pedicle. On the anterior surface of the uterus were two other tumors, considerably smaller. On the left side of the uterus another mass was to be felt, of an irregular, oblong shape, also quite movable. This mass seems to me to have been the same one which was felt through the vagina descending into the pelvis, at the two times the patient was first examined, as it was not felt outside at those times, and in all probability it was drawn out of the pelvis by the powerful contractions of the uterus, while the pelvis became occupied by the breech. Internally the body of the uterus was found antverted, movable, and its connection with the tumors outside easily ascertained through bimanual examination.

Dr. JOHN HOMANS remarked that women with fibroids are generally sterile. After labor these tumors frequently atrophy and disappear. The case mentioned by Dr. Berlin is of great interest. A hard mass filled the vagina and pelvic outlet, and it was almost impossible to get one finger by it and feel the os behind the pubes. In this case Dr. Homans advised waiting till labor commenced, because nature often gets us out of tight places. He thought that it might possibly be necessary to do Porro's operation. When, however, the preparatory pains of labor came on, the tumor had

entirely disappeared, and the os was found in its normal position. Nature did it much better than it could have been done by us under ether. Expectation is the best way to treat these complications.

Dr. Homans reported a case occurring in the practice of Dr. C. D. Homans. A lady with a fibroid originating by a broad pedicle from the posterior lip of the uterus was confined the first time at the age of thirty. The tumor of the size of an elongated fist filled the vagina; the labor was tedious and was finished by forceps. There was a dent in the child's temple, caused apparently by the violent pressure against the pubic or iliac bones, by the tumor squeezing the head. The dent is still plainly visible at the age of fourteen.

At the second, third and fourth confinements, the tumor was of about the same size as at the first, delivery in each case was instrumental and difficult. There has never been serious menorrhagia. Unfortunately the patient has never allowed any examination to be made except during the process of delivery.

Another case in which a fibroid the size of a small orange had caused excessive anemia from almost constant menorrhagia, was cured by marriage and pregnancy, the tumor entirely disappearing after confinement.

Dr. REYNOLDS asked if the color of the vulva was pathognomonic of pregnancy, and if it varied in different women.

Dr. CHADWICK replied that he thought it was pathognomonic when distinct. Among several hundred cases, he had made a mistake but once. He said that it was most marked in those women who had had several children. He considered it an important factor in making a diagnosis.

#### THE AMERICAN DERMATOLOGICAL ASSOCIATION.

The Ninth Annual Meeting of the American Dermatological Association was held at the Indian Harbor Hotel, Greenwich, Conn., August 26th, 27th, and 28th, 1885.

#### WEDNESDAY MORNING SESSION.

The meeting was called to order at ten o'clock by the President, Dr. W. A. HARDAWAY, of St. Louis.

#### A CASE OF TUBERCULO-ULCERATIVE SYPHILIDE OF HEREDITARY ORIGIN.

By Dr. J. E. GRAHAM, of Toronto, Canada.

The patient is a girl twenty years of age. The skin of the right arm from the wrist to the elbow is little but cicatricial tissue. It presents elevations and depressions, and in places is covered with thin scales. The hand is not involved and the affection does not extend deeper than the subcutaneous areolar tissue. For three or four inches above the elbow, the arm is atrophied and covered with cicatricial tissue. At the upper border of the cicatricial tissue, there is an ulcer three-fourths of an inch wide, which encircles the arm. Above this there is sound tissue, no nodules are present. The left clavicle presents, about its middle, a swelling and ulceration about the size of a silver dollar. This was the result of a blow. There is no copper-colored appearance. The heart and lungs are healthy and the urine normal. Investigation of the family history showed that the mother was apparently healthy. Three of the patient's sisters, all younger than herself,

were healthy. The father died from pneumonia when the patient was eighteen months old; it was subsequently learned that he had also had syphilitic ulceration of the throat.

The treatment consisted in the local application of a mild mercurial ointment and the internal use of bi-chloride of mercury and iodide of potassium. The condition steadily improved, and in the course of six or eight weeks, the ulceration had healed. The patient at that time passed from observation.

The speaker referred to the difficulties of diagnosis in this case, as there was a complete absence of specific history, the facts in regard to the father not being learned for some time after the case had been under treatment. There was no history of any previous evidence of hereditary syphilis, but taking all the facts into consideration, the doctor thought that there could be no doubt as to the correctness of the diagnosis.

Photographs showing the condition were exhibited.

#### DISCUSSION.

DR. R. W. TAYLOR, of New York. — There are a number of important points brought up by this paper. First, as regards the family history. The mother had no syphilis, but the father had syphilis. It is now generally conceded that syphilis can be communicated to the child without infection of the mother, and I believe that I was the first one in America to call attention to this fact. I have seen this a number of times, and this has been in cases where a most careful examination of the mother has been made, and where the observations have been continued over a series of years. The doctor states that he could obtain no history of early manifestations of hereditary syphilis. This is not uncommon, but I believe that there is usually some indication of specific taint, but this may be so slight as not to excite notice, or its exact import is not recognized. These may pass away, and, in the course of six months or a year, the ulcerative lesions appear, but it is not uncommon for the child to go to the age of from six to eighteen years without exhibiting this condition. I have reported a case of a girl whose mother had syphilis who had exhibited signs of hereditary disease during her early years. When about fifteen years of age, she had, following a cold bath, the development of ulcerative gummatous tumors all over the body. Another point is the role of traumatism. I have frequently noted these conditions following traumatism.

DR. C. HEITZMAN, of New York. — Every one has seen cases similar to the one reported. I have seen cases in which I was unable to determine at first sight the nature of the affection. The diagnosis lies between syphilis and scrofula. A man, aged twenty, came to me with a condition similar to that described by Dr. GRAHAM, affecting the right groin. The ulcer was ten inches in diameter. I was unable at first to make the diagnosis.

DR. GREENOUGH, of Boston. — I should like to refer to the practical point to which Dr. Taylor has called attention, and that is the possibility of the father infecting his progeny without the mother showing any signs of syphilis. Within the past two months, I have seen a woman who has lost three children in succession from hereditary syphilis, yet she is strong and apparently perfectly healthy, and has never shown any signs of syphilis. This woman has been under observation for six or seven years.

DR. J. C. WHITE, of Boston. — I think that in many of these cases it is impossible to make the diagnosis at once.

DR. L. A. DUNNING, of Philadelphia. — There are certain cases in which it is almost impossible to express a positive diagnosis at first. The result of treatment in causing a rapid cure in the case described would certainly incline me to the opinion that this was a case of syphilitic disease. I have, however, never seen a case recover so quickly.

DR. J. N. HYDE, of Chicago. — As regards the remarks of Dr. Taylor, I will say that I have seen cases which have convinced me that whilst it is not the rule, still occasionally syphilitic children are born where, so far as observation can be made, no evidence of syphilis in the mother can be detected. As far as the general health is concerned, I cannot say that I have seen vigorous healthy women the mothers of syphilitic children. The women are usually pallid and weak, although there may be no symptoms which can be ascribed to syphilis.

I see inherited syphilis in infants constantly, but I have never seen inherited syphilis manifesting itself in advanced years, or if I have, I have failed to make the proper diagnosis. The more I see of syphilis, the more am I satisfied that in its origin, heredity does not amount to very much. The accidental cases of syphilis are very common. I have seen the initial lesion of syphilis on the head of a penis where it was unquestionably due to inoculation from the finger of the surgeon in catheterization. I have no doubt that the case described was one of syphilitic trouble, and, as Dr. Dunning has said, the result of treatment unquestionably points in that direction. There are no cases which yield so readily as old cases of untreated syphilis. As to pronouncing it a case of hereditary syphilis, my experience would not permit me to do so.

DR. W. A. HARDAWAY, of St. Louis. — I think that it is unwise to base our diagnosis on the results of internal treatment. That a case gets well under anti-syphilitic treatment is not proof that the affection is specific in its nature. Local treatment is often all that is necessary.

DR. R. W. TAYLOR, of New York. — Dr. Hyde has made the statement that these women, apparently un-syphilitic, who have borne syphilitic children, have, in his experience, been pallid and weak. I entirely disagree with him on that point. I find such persons in robust health.

The next paper was entitled

#### CLINICAL NOTES ON PSORIASIS.

By DR. F. B. GREENOUGH, of Boston.

The paper was founded on the records of 394 cases of psoriasis. This number occurred in about 15,000 cases of skin disease examined, and represented about two and one-half per cent. 205 cases occurred in males and 188 in females. Several tables of statistics were presented, showing when the cases first came under observation and the age at which the attack was first observed. A large proportion of the cases was first attacked with psoriasis between the ages of ten and forty years, but the fact that one-seventh of the cases showed symptoms of psoriasis before the age of ten years was not in accordance with previous observations. In 97 cases, the speaker had been able to get reliable evidence in regard to the family history. In 31 cases, psoriasis had existed in a near relative, but

in 66 cases, the patients felt sure that the disease had existed in no other member of the family.

The amount of pruritus complained of in psoriasis varies, but it is rarely a prominent symptom, although in exceptional cases, it is very severe. He had never seen any eruption on the hands or feet resembling psoriasis, with the exception of eczema, which was not syphilitic.

In regard to treatment, some cases do well, while others do not. There is no specific. What will benefit one case, may make another worse. In his experience, tarry preparations, especially the oil of cade, have been most efficacious. Great comfort may be afforded by the use of emollients, cod-liver oil is one of the best applications. Cod-liver oil and oil of cade (equal parts) is a common prescription. Chrysarobin is a powerful remedy, but has the disadvantage of destroying the clothing. On the face and scalp it is apt to produce dermatitis. The internal administration of arsenic in some cases is of benefit. Even after apparent recovery, there is great danger of relapse. (This paper will appear in full in the next number of the JOURNAL.)

Dr. HYDE.—Did any of these cases have the eruption on the palms of the hands?

Dr. GREENOUGH.—None of these cases presented that condition.

Dr. HYDE.—I think it would be well to drop the idea that psoriasis occurs on the palms of the hands, at any rate exclusively. In all the cases in which such appeared to be the case, I have been able to make some other diagnosis.

I have observed one or two cases of psoriasis of the head in individuals bald on the top of the head, and in these instances, the eruption confined itself to the portions covered with hair.

Dr. L. A. DURING.—The reader of the paper in referring to the diagnosis did not allude to the difficulty sometimes experienced in diagnosing scorrhoea capitis from psoriasis. I have found considerable trouble in the diagnosis, particularly in young girls. In these cases the eruption was confined to the scalp.

Dr. A. R. ROBINSON.—In regard to the diagnosis of favus and psoriasis, there is usually no difficulty. I do not agree with the author in regard to one of his points of diagnosis. In the early stage, you do not find moisture when the crust is removed. There is a shiny appearance. It is only in advanced stages that ulceration is present.

I agree with the speaker that psoriasis always occurs in small spots, at first not covered with scales. I consider it primarily an affection of the rete. While it is true that psoriasis often disappears without producing pigmentation, yet there may be discoloration found on the lower extremities, particularly where there is a varicose condition of the veins. In some cases where there are only a few patches of psoriasis limited to the lower extremities, it is often difficult to make the diagnosis, unless there is involvement of other parts of the body, or you have the history. There are other cases of acute psoriasis which closely resemble acute eczema. In reference to the palms of the hands, whilst we do not see cases of psoriasis limited to this situation, yet I am sure that cases have been shown in which the palms of the hands have been affected in connection with other portions of the body.

Dr. J. C. WHITE, Boston.—I agree with the previous speakers in regard to the difficulty of diagnosing

between psoriasis of the scalp and seborrhoea. In some cases the diagnosis cannot be made for months. In all parts of the body, pigmentation may follow psoriasis, but never over large areas. In diagnosis, I do not lay much stress on the location of the eruption. When the eruption is sparse, it is more apt to affect the extensor surfaces.

I should like to call attention to one termination which I have seen in three cases, and that is a degeneration into epithelioma.

Dr. R. H. MORRISON, Baltimore.—I see a great many cases of psoriasis, and in our dispensaries we have many negroes under treatment, but I can recall only one or two cases of psoriasis in the negro. In such cases, there is a loss of pigment.

Dr. G. H. FOX, New York.—Too much stress is, I think, laid on the general rule that psoriasis occurs most frequently on the extensor surfaces, the knees and elbows. It is a notable fact that in general psoriasis, the vicinity of the knee and elbow escapes. Many cases of psoriasis occur in weakly subjects, while on the other hand, many cases of eczema may appear in robust persons. In every individual case, the better the patient's health, the less likely is he to suffer from a recurrence of the affection.

I have been very successful in the treatment of psoriasis and in its management, I adopt the teaching of the late Tilly Fox. He laid stress on the point that in psoriasis, as in other inflammatory affections of the skin, and also in lupus, the first thing to do is to lessen the congestion of the skin. I do not do this by adopting the alkaline treatment, but by restricting the diet. I do not devote special attention to the starchy and saccharine elements of the food, but cut off the meat and order a diet of fruits and vegetables in the summer, and in the winter, give a carefully restricted diet. Tea, coffee, tobacco and stimulants of all kinds are to be cut off. By so doing more will be accomplished than is obtained by using arsenic and local applications at the start.

In regard to local remedies, I never use tar in the treatment of psoriasis. With the application of chrysarobin made at the proper time, there is no necessity for the use of tar. I have seen many cases, in which this drug did no good, but this was because the application was made when the patches of psoriasis were in a congested condition. If the acute congestion is lessened, chrysarobin will produce beneficial results.

Dr. C. HEITZMAN, New York.—One of the most important points after making the diagnosis, is to decide as to the acuteness or chronicity of the affection. If it is acute, local applications are to be avoided. If the case is chronic, chrysarobin may be used with advantage, at least temporarily. It is not a cure. I agree with Dr. Fox that restriction of the diet is important for the purpose of lessening the congestion. Tar cannot be dispensed with. Chrysarobin remedies the disease for a time, but in a few months it returns. There is nothing like tar to prevent the recurrence. No mention has been made of pyro-gallic acid, which does good in some cases. There are, however, some cases which cannot be treated successfully with any remedies. The disease will steadily grow worse.

Dr. W. A. HARBANAWAY.—I believe that in psoriasis, we have a disease situated in the skin itself. It is frequently hereditary. The same sort of skin may be transmitted just as a certain color of the hair or of the eye may be transmitted and then any exciting cause

may develop the psoriasis. Traumatism is frequently the exciting cause. I have seen psoriasis follow eczema. It is not unlikely that in seborrhoea of the scalp, there may be the development of psoriasis. Internal causes may produce it. I have seen the excessive use of oatmeal produce typical psoriasis. In the treatment of psoriasis it is important to regulate the diet. I cut off meats and aid digestion in all possible ways. As a local application, I believe that chrysarobin with salicylic acid is very useful in chronic cases. Arsenic is useful on account of its action on the skin. I have employed chrysarobin in liquor gutta-percha, and in gelatine paste. This treatment may be followed up by the application of sulphur ointment. In psoriasis of the scalp, sulphur is quite an efficient remedy.

Dr. GREENOUGH.—I did not intend to cover the entire ground of psoriasis in my paper. The omission of a consideration of seborrhoea was an oversight. In regard to pigmentation, I referred especially to those cases of psoriasis of the trunk which were most apt to be confounded with syphilides.

#### CASES OF ANGIOMA PIGMENTOSUM ET ATROPHICUM.

By Dr. J. C. WHITE, of Boston.

Two cases were reported. The first patient was a young man seventeen years old, and a Russian Pole by birth. Freckles appeared on his face before he was two years of age. These increased in number until the age of six. When the telangiectatic condition first appeared is not noted. When seen, the patient was well developed and apparently in good health. He has, however, grown slowly, and is now no larger than a boy of twelve. The hair of the head is abundant and intensely black. The eyes are also black.

Present condition. Melanosis. The forehead and lower portion of the face are of a dark brown color, and on close inspection small spots of a darker color are seen. The whole trunk is as dark as the skin of a dark Spaniard. The scrotum is very black and the penis and glans present dark spots. The arms and hands are thickly spattered. The legs are also affected. On the right thigh there is one spot of dark color, covered with rather long hair. The mucous membrane of the mouth and pharynx is free from melanosis.

The atrophic condition. On the right side of the face occupying one-half the surface, is a sharply defined area of white cicatricial looking skin. Similar areas are seen on the other cheek, forehead and about the mouth. A few white spots are seen on other portions of the body. The sensibility of the affected areas is decidedly lessened.

Telangiectasis. Over parts of the face there are bright red spots, varying in size from a pin's head to a pea. These are most noticeable in the atrophied portions. Within the lids, there are two angiomatous new growths. Several vascular twigs are also seen on the face. A few red points are found on the general surface.

The second case is a brother of case 1, aged three years, born in New York. When eighteen months old, little colored freckles were noticed on the face. Since then the condition has been developing. His hair is dark brown and his eyes are black. The face is covered with numerous dark brown freckles. The spots are so close together that at a little distance, the skin has a uniform color. In some places, the spots are slightly elevated. The backs of the hands are covered with dark brown spots, elsewhere the skin is

clear. There are no leucodermic spots and no angiomatous condition.

From a study of these cases, I conclude that in the beginning, the development of these spots cannot be distinguished from ordinary freckles. Gradually the spots multiply until they involve a considerable portion of the skin. It is probable that several years may advance without other manifestation of the disease. The telangiectatic condition is probably secondary. In the first case it is most developed in the atrophic portion. It is probable that in this case there will be hypertrophy of the epithelium and final transformation into epithelioma. This has been the result in the thirty-three cases which have been reported.

#### DISCUSSION.

Dr. TAYLOR.—I think that there is a direct relation between the red spots and the macules. The history of the cases which I have seen, have been, first a rash, then the red spots and then the macules. In one case the telangiectasis followed exposure to heat.

Dr. WHITE.—I recognize a great difference in this disease as described by various writers, but I must insist on the correctness of my own observation. The younger child has exhibited none of the precedent hyperemia which has been noted in some cases. The patient has been observed after exertion and when exposed to intense heat, but there has been no hyperemia. The same is true of the first case as far as is known. In the second case, which is still developing, there is no enlargement of the vessels.

#### WEDNESDAY.—EVENING SESSION.

#### RELATIONS OF LUPUS VULGARIS TO TUBERCULOSIS.

By Dr. J. N. HYDE, Chicago.

The speaker began with a detailed statement of all the cases of lupus reported to the statistical committee of the American Dermatological Association, during the last seven years, and compared the frequency of the disease in this country with that reported in the Vienna hospitals. He then gave details of twenty consecutive cases observed by him in Chicago.

The clinical deductions from these records were then added, showing, according to the author, that there was a remarkable absence of pulmonary tuberculosis, scrofula, and allied diseases in the family histories of the last twenty cases reported.

The teachings of the two schools, represented in the past by prominent German and French authors were then referred to, and finally, the later investigations, demonstrating that lupus vulgaris was the result of bacillus infection, not to be differentiated in external appearance of the parasite from the bacillus tuberculosis.

The following clinical facts were then cited in support of the later teaching of this subject as bearing on the vital point in the author's argument, that is, that lupus vulgaris was not the result, as had long been taught, of tuberculosis or other systemic diathesis, but was the product of a local infection by bacilli, entirely unassociated with any constitutional evidence of diathesis or predisposition.

(1) The unimpeachable character of the family record in by far the larger number of cases of lupus vulgaris.

(2) The fact that the disease is in its inception a disorder of the period of childhood, when for the most part, the habits of the child are favorable to infection.

(3) The several seats of predilection are those most favorable to such infection.

(4) The failure of the disease to spread by inheritance.

(5) The remarkable tendency of lupus vulgaris to entaneous limitation.

#### THE TREATMENT OF LUPUS BY PARASITICIDES.

DR. J. C. WHITE. — reviewed the evidence in favor of the parasitic nature of the affection. All previous plans of treatment which had proven most successful were those which would have the effect of destroying any parasite which might be present.

A number of cases were then reported in which the local use of corrosive sublimate in the strength of two grains to the ounce of water or unguent had been used with beneficial results. The ointment was especially recommended. It had been rarely necessary to prolong treatment over two months. As regards the permanency of the cure the author was unable to speak, as the experiments had been continued for only eighteen months.

DR. SHERWELL. — I would express my profound disbelief in the parasitic nature of the disease, and I do not know that the theories of Koch have been entirely proved. It seems to me that lupus and the scrofulous diathesis represents some form of syphilitic hereditary influence.

DR. WIGGLESWORTH. — I would suggest that the oleates might be more efficient than ointments, on account of their penetrating power.

DR. HYDE. — At the last meeting of the Association, Dr. Taylor suggested the use of a solution of corrosive sublimate in tincture of benzoin. I have used this in cases of lupus and in cases of infecting chancre. It makes an excellent application. In regard to the syphilitic origin of this affection, I would say that I recognize the fact that inherited syphilis is inherited syphilis, and has no relation to this or other diseases.

The next paper was by the president, Dr. W. A. HARDAWAY, of St. Louis, on

#### THE TREATMENT OF PORT-WINE MARK BY ELECTROLYSIS.

In the treatment of this affection, the object is to excite sufficient inflammation to cause occlusion of the vessels. Electrolysis seems to be the most convenient way of doing this. At first the speaker had used a bundle of needles, but he now employed only the single needle. It is important to allow a period of some weeks to elapse between the applications. The histories of three cases were given in which this method had been employed.

#### DISCUSSION.

DR. WHITE. — I have used this method in one case, and have produced considerable improvement.

DR. WIGGLESWORTH. — I have seen good results from cutting the vessel in two places and using a preparation of iron, thus closing up the dilated vessels. The worst case that I have ever seen was that of a lady whose face was so red that it was very noticeable. I treated her for three or four years, and when I got through she was quite a handsome woman.

DR. FOX. — We all admit that the so-called spider cancers and telangiectases are amenable to treatment of different kinds, but when we come to the port-wine

marks we find a difference. I think that better results can be obtained by electrolysis than by other measures, but it does not remove the trouble entirely.

I have used the treatment with puncture and carbolic acid with fair results. I have sometimes passed the electrolytic needle deeply, endeavoring to strike the artery of supply, and sometimes have produced a decided effect.

DR. DEXSLOW. — I recently saw a case of port-wine mark on the labia majora of an infant. This had ulcerated when the child was brought to me; as a temporary measure I applied the liquor gutta-percha. In two days, without other treatment, the whole mark sloughed out, leaving nothing but a simple ulcer which completely healed in the course of three weeks.

DR. HARDAWAY. — The advantage of the electrolysis is that it is manageable. A practical point might be referred to, and that is, if after the operation, the part should be frequently mopped with hot water, the inflammatory disturbance will be greatly lessened.

#### REMARKS ON A MOOT POINT IN THE ETIOLOGY OF PSORIASIS.

By DR. S. SHERWELL, of Brooklyn.

The speaker had been struck by the great diversity of opinion in regard to the general health of those affected with psoriasis, and in order to arrive at something like a consensus of opinion on the subject, he had referred to the writings of most of the authorities in dermatological matters. Brief extracts from various writers were then given. The evidence thus obtained strengthened the doctor's opinion that the patients with psoriasis were generally in good health.

He thought that the theory of Piffard, who believes that the rheumatic diathesis is a great exciting cause of psoriasis was the most rational theory that had been advanced.

#### THURSDAY. — MORNING SESSION.

At the business meeting officers were elected as follows: —

*President:* Dr. E. Wigglesworth, of Boston, Mass.

*Vice-Presidents:* Dr. I. E. Atkinson, of Baltimore, Md., and Dr. A. R. Robinson, of New York, N.Y.

*Secretary:* Dr. G. H. Tilden, of Boston, Mass.

*Treasurer:* H. W. Stedwagon, of Philadelphia, Pa.

Dr. E. B. Bronson, of New York, was elected to membership.

The next meeting will be held, beginning the last Wednesday of August, 1886, at Greenwich, Conn.

Dr. G. H. Fox gave a brief description of two cases of

#### DYSIDROSIS.

The first case, for want of a better term, he classed under this heading. The patient was twenty-nine years of age and had always perspired freely. Four years ago the eruption began on the palms of the hands and had persisted. The soles of the feet had also been affected at one time. The skin of the hands was decidedly thick, and had a dark hue and was dotted with numerous elevations of epidermis, averaging in size that of a hempseed. The patient had never seen any moisture in connection with this. There had been no itching. The skin never peeled off. Punctures with a needle revealed no serum or fluid of any kind.

The second case was that of a woman, aged forty-five years, a cook, whose general health was good.

The present trouble began five years ago. The eruption is on the face and consists of numerous large and small vesicles containing clear fluid.

Dr. ROBINSON, — These latter cases are not infrequent, and may persist for months and years. They consist in obstruction of the sweat duct in the corium. They never cause inflammation around them, although sometimes they may be surrounded by a little areola as the result of pressure. The symptoms which they present do not at all correspond to those of dysidrosis as described by Hutchinson and Tilbury Fox, as belonging to dysidrosis of the palms.

[To be continued.]

## Recent Literature.

*The Microscope in Botany. A Guide for the Microscopical Investigations of Vegetable Substances.* From the German of DR. JULIUS WILHELM BEHRENS. Translated and Edited by REV. A. B. HERVEY, A.M., Assisted by R. H. WARD, M.D., F.R.M.S. 8vo. pp. 166. Boston: Cassino, 1885.

This book, issued in an expensive and handsome manner by the publishers is an excellent translation of a good German manual. We think, indeed, that less luxury of paper and press-work might have so essentially lowered the price as to give the book a wider usefulness. After all, for a work intended for frequent consultation the German custom of printing on light, but fine paper, has some advantage, which those who lift Dr. Hervey's heavy volume will think of enviously.

The translation is very smooth and sufficiently accurate; the idea has apparently been to express well the ideas and meaning of the original, rather than to achieve a painful literal exactitude in the rendering. And in attempting this the translator has met with success.

Besides the translation, the volume also contains a considerable number of addenda, by Dr. Hervey and Dr. Ward, which are duly distinguished in the text by the interpolation of brackets. The increments are truly American, for they consist largely of a series of recommendations of American microscopes and microscopical accessories. It seems a pity to mislead students on such an important matter, as is done by striking out the original account of the European microscopes and substituting a set of praises of American stands, praises which exhibit more patriotism than judgment. On the other hand, many of the lesser American devices are capital; but we warn readers against the Syracuse watch-glasses.

With the exception of the first chapter (on the microscope), there have not been many alterations. The directions for the making and preserving of microscopical preparations are given with clearness and good sense. The best part of the book, however, that which gives it individuality and value, is the portion, Chapters IV and V, dealing with what we may call micro-chemistry for botanists. This is a thoroughly original compilation of the extremely scattered literature of a difficult subject. The matter is treated from two sides; first, in Chapter IV, the author goes through the somewhat lengthy list of reagents, and second, in Chapter V, he takes up the various substances, the botanist encounters under the microscope, and details the va-

rious methods of studying them. In connection with this, is given for each substance references to the principal literature concerning it.

Before closing, we wish also to commend the hints on drawing given by Behrens. To conclude: the volume is meritorious, and we hope it will contribute much towards the advancement of scientific botany in this country. It is a field we have sadly neglected thus far.

*The Technology of Bacteria Investigation.* By CHAS. S. DOLLEY, M.D. Boston: S. E. CASSINO & Co. 1885.

This is a book presented with the hope that it "will stimulate careful study of the Schizomycetes by American investigators." If it fulfils this hope we are mistaken in our estimate of the work. It may be of service to the general reader in medicine, but its use by the beginner is likely to create confusion.

The various methods employed in bacteriology are given, but with no sufficient comment which would enable a judicious selection of them to be made. This is a point which cannot be ignored, in view of the constant and lengthy additions to the subject that are almost daily being published. The form of the book is open to criticism as being unsuited to a manual for the laboratory table, and it certainly was not necessary to fill a third of its bulk with bibliography, by printing it in the same type with the text. H. C. E.

*Manual of Diseases of the Ear; for the use of Students and Practitioners of Medicine.* By THOMAS BARR, M.D. Lecturer on Aural Surgery, Anderson's College, etc. Glasgow: James Maclehose & Sons. 1884. Small 8vo, pp. 518.

This is a most admirable manual of the subject of which it treats, and better adapted for giving thorough, scientific knowledge than any of the lesser works with which we are acquainted, and serves the purpose for which it was intended, to give students a reliable textbook in moderate space, extremely well. It fills a long-felt want. It avoids on the one hand conciseness which is too apt to be uninteresting and incomplete, and on the other hand, wearisome diffuseness and unpractical scientific accuracy.

The arrangement of the work is admirable on the whole, and the subjects are easy of reference; in one or two places, perhaps, a little tendency to introduce new names is noticed. The illustrations, although few in number, are exceedingly well done, and at the end is a list of formulae, a favorite bit, as it has always seemed to us, a dangerous refuge for the medical student and young practitioner. On the whole, the book receives our hearty endorsement.

— Dr. Henry William Reichardt, Professor of Botany in the University of Vienna, committed suicide on the 11th inst., by hanging himself in a fit of temporary insanity. Dr. Reichardt was graduated as Doctor in Medicine at Vienna in 1860, became Assistant Professor of Botany in the same year, and in 1866 was named Deputy Keeper of the Imperial Botanical Cabinet. In 1879, he succeeded Dr. Fenzl in the chair of Botany at the University, and also as Chief Keeper of the Botanical Cabinet and Vice-President of the Vienna Horticultural Society. He was fifty years old at the time of his death.

## BIOLOGY, PREPARATORY TO MEDICAL STUDIES.

Is the battle between hostile factions of educators on the subject of the best intellectual preparation for the duties of active life it is not, perhaps, within the province of the medical journalist to intrude. We wish, however, to call attention more fully than we have done before, to a new path leading into the study of medicine, which for those who find it to their taste, seems to us to offer an excellent preparation for doing a kind of work which medical science needs. There is, perhaps, some truth in the criticism that the work of the various different schools for professional training tends to fall into ruts, and that the men who are graduated look upon the problems which are to confront them from one common, and that a partial point of view. Anything, then, which being in the nature of sound learning, tends to give variety to the mental attitude and equipment of a profession, is to be welcomed.

The Massachusetts Institute of Technology has always been to some extent a feeder of the Harvard Medical School. It is only comparatively recently, however, that it has designed and prepared one among its courses especially for the training of young men for the study of medicine. This course is called "Biology, Preparatory to Medical Studies."

It covers, like the other courses in the school of industrial science, a period of four years. Of these, the first is identical with the other courses, and is devoted largely to subjects of a general nature, such as mathematics, chemistry, drawing, literature, history and the modern languages. In the second year the work begins to diverge into a biological channel, although the general subjects already alluded to are not discontinued. A large room, well adapted to laboratory uses, has been assigned to this course, and here the students are made practically familiar with living things, beginning with the simplest organisms, such as the amoeba, mould and yeast fungus, and working up gradually to more complex forms. There is a minimum use of textbooks, and the eye and hand of the student, assisted by the microscope, the scalpel, and similar appliances, are the media through which the mind is brought directly

in contact with the phenomena of living things. Comparative anatomy, studied entirely by dissections, first of the lower animals, and then of the mammalia, histology, experimental physiology, embryology (studied for obvious reasons chiefly in the chick, but forming a most complete groundwork for the study of the human embryo), and finally, what may be called transcendental biology, including such topics as natural selection, mimicry, heredity and instinct, constitute the large work of the course. Meanwhile, the more general subjects are not neglected, since physics with laboratory work, chemical methods and sanitary chemistry, as well as the modern languages, constitutional history and political economy are also included.

This course of study, which has but just got upon a fair working basis, has during the last year had a number of students who with more or less zeal for the subject, have been working in its laboratory. Only a comparatively small number of them, however, are men who have medicine as a calling definitely in view, and are following the biological course as a means to that end. It is evident that the course, especially if kept up to a high standard of thoroughness, can never be popular with that unfortunately large class of men who are seeking the shortest cut to medical practice on a money-making basis. Moreover, the intellectual trend of a large number of the men who seek a liberal preparation for medical study, will lead them as heretofore through the colleges and universities. Doubtless, however, some of these latter may, after graduation, take the last two years of the biological course, and thence pass perhaps into the second year of the medical school to spend three years there, thus completing the four years' course. In this way but one year more than the ordinary term would be expended. Others whose means permit and who realize how little most men can accomplish in the way of medical practice in our large cities, before the age of thirty, may easily find time after graduation from college for the two years of biological work and four years at the medical school, and then have two years to spare for hospital service or foreign study.

We have spoken chiefly of the course established in connection with the Massachusetts Institute of Technology, because we have had an opportunity of witnessing its appliances for work and of learning from the accomplished teacher in charge of the department of his purposes and aims for the students under his instruction. We understand, however, that a similar work is going on in other cities. The Johns Hopkins University, which is, perhaps, to be one of the leading centres of medical teaching in this country, is giving, as is well known, especial attention to and providing special facilities for, biological studies. The Sheffield Scientific School of Yale College has already equipped in a similar course a number of men for the medical profession.

The great "Dark Continents" of medical science to-day comprise among others that unexplored domain lying between the boundaries of chemical and physio-

logical science. Another region, hitherto unknown, but now occupied by more numerous investigators and giving hope of some contribution to our knowledge of disease, is the study of the lower organisms. For these and kindred researches we look with hope to some of the men who bring into medical science such training of brain, and eye, and hand, as may be gained by zealous and earnest work in the field of biological science.

#### THE UNCERTAIN ANTI-MALARIAL PROPERTIES OF THE EUCALYPTUS.

The reputed properties of the *eucalyptus globulus* as affecting the prevalence of malarial diseases in climates where the tree can be cultivated successfully, have attracted considerable attention on the part of hygienic observers within the past twenty years or more. Observations in Italy and in Algeria gave promise of remarkable protection afforded by means of plantations of *eucalyptus*, and trees were largely distributed by the Italian Government in 1875 to the inhabitants of the Roman Campagna, where forests were planted with the confident belief in a future immunity from malarial poison. The singular properties of the tree have been attributed to the wonderful rapidity of its growth, and the consequent drainage of the surrounding soil, and also to a certain specific quality afforded by the exhalations of its leaves. The former has usually been accepted as the more reasonable explanation.

Prof. Tommasi Crudeli<sup>1</sup> adduces certain observations in opposition to this belief. The summers of 1881 and 1882 were notably dry in the neighborhood of Rome, and also exceptionally free from malarial diseases. During this period of unusual health a serious epidemic of malarial fever broke out at Tre Fontani, where a monastery of Trappists is located. At this place these monks had carefully planted and watched a grove of *eucalyptus* trees, to which they had also attributed their temporary immunity from malarial disease. To confirm the experiment a colony of convicts had been established in that part of the estate which was believed to have been made healthy in consequence of the forest of *eucalyptus* trees. In the fever season of 1880, nearly all the colony of convicts were attacked by fever, and notwithstanding the careful precautions taken in the summer of 1882, every inhabitant was attacked, both the monks and the convicts suffering severely.

Professor Crudeli says: "We must remark the singular contrast presented by the sanitary state of the whole Agro Romano in 1882, and the great development of malaria which took place in this plague-stricken spot in it, which so many, both in Italy and abroad, declared to be already cured by *eucalyptus* plantations, and a wisely-conducted high cultivation, and it cannot fail to strike all those in Italy who are interested in the vital question of the improvement of malarious soils.

"The facts prove to what risks of mistake we expose ourselves if we hold *a priori* that the methods which have resulted in a permanent improvement of one malarious locality can be usefully applied to all."

As to the best method of improving the condition of any given soil with reference to the development of malaria, he presents the following proposition:—

"The condition of such a permanent improvement is that of so modifying the physical condition and the chemical composition of the soil as to render it incapable of producing the malarial ferment."

In an address before the International Medical Congress at Copenhagen in 1884, Professor Crudeli stated certain conditions as essential to the development of malarial poison.

- (1) A temperature not less than 20° C.
- (2) A moderate amount of permanent moisture in the soil.
- (3) Ready access of oxygen to the strata which contains the ferment.

The efforts of man must be confined to the destruction of two of these conditions, by excluding the oxygen by means of topdressings of compact soil, and also by removing the subsoil water by drainage.

Instances were also cited wherein the French Government had made inquiries in Algeria, and shown that the woods or groves of *eucalyptus* established there had not affected the hygienic condition of the locality in the slightest degree.

#### MEDICAL NOTES.

—The amount of quiet heroism shown, when occasion arises, by members of the medical profession is little understood, and, as a rule, little regarded outside its ranks. The profession, as a whole, is exposed to the attacks of a large number of wrong-headed persons, who, in the advocacy of their petisms, heap a vast amount of undeserved obloquy upon it. We are called heartless and mercenary, and it is proclaimed that our deeds of charity are done in the hope of indirectly reaping some pecuniary reward, and that we take a "fiendish pleasure" in inflicting pain; yet those who know the inner life of hospitals, and the regular routine of general practice, know how much self-denial and how much silent courage are daily displayed. It is well for us and well for the public, that sometimes a conspicuous act of courage is brought prominently forward, and receives the recognition which it deserves; and it is, therefore, with great pleasure that we note the official announcement, that "the Queen has been graciously pleased to confer the Albert Medal of the Second Class" upon Edward Charles Thompson, Esq., M. B., University of Dublin, L.R.C.S.I., and surgeon of the Tyrone County Infirmary, for conspicuous heroism displayed in endeavoring, on April 4th, 1885, to save the life of a child, named Herbert Mitchell, suffering from diphtheria." Dr. Thompson is to be heartily congratulated on the reward which his courageous conduct has deservedly received. — *British Medical Journal*.

<sup>1</sup> The Practitioner, July, 1885.

— His Honor, William McGregor, M.D., C.M.G., has been appointed by the Imperial Government administrator of the government of the colony of Fiji. The *Australasian Medical Gazette* reprints an English translation of that portion of his speech at the annual meeting of the chiefs in May last, which relates to sanitary affairs. In it, Dr. McGregor tells the chiefs that during the past year there were actually 2,562 more deaths than births, and that the principal, if not the sole immediate, cause of the great decrease in population, was an epidemic of whooping cough. The fatality in the aboriginal population from this epidemic of whooping cough was much less serious than that from a similar epidemic of measles a few years ago.

— According to the New Orleans *Picayune*, Pension Commissioner Black has turned out three highly respected members of the board of examining surgeons, and undertaken to appoint in their places one man now under indictment and two others so young to fame as to be unknown by the public.

— *La Enciclopedia Habana* gives an account of a case of catalepsy in a young soldier of twenty-two, now in the military hospital of San Ambrosio, in Cuba. He has remained in a cataleptic condition for fourteen months.

— The euca plant from which the new local anæsthetic is obtained, is reported as being planted on a large scale in Ceylon.

## Miscellany.

### THE INTERNATIONAL CONGRESS.

WE are glad to gather from our latest information from the United States that the prospects of the International Medical Congress meeting have improved. It would be strange indeed if such a project in such a country could fail of a successful issue. The organization of the profession there may be somewhat different from what it is in older countries, and there may be ideas of professional freedom which exceed ours. There may even be questions of a personal character involved in the arrangements to be made; but that the arrangements will be great, and conceived in a magnanimous spirit, and worthy of the profession of a great country may, we trust, be taken as already secured. One guarantee of this hopeful view being realized is to be found in the nomination of Dr. Flint as President of the Conference. Dr. Flint is so well known amongst us, not only by his works, but by his genial and dignified presence, that the English profession will need no other proof of the oneness of the profession in both countries, both in its spirit and its practice, than the selection by the American Medical Association of this distinguished physician for the chair of the Congress. It will be the same in other European countries. Dr. Flint has not hesitated to take long voyages in promotion of the international co-operation of the profession. He was as active at Copenhagen as in London, and we doubt not that the European response to the American invitation will be wide and hearty. The little differences which have arisen in America are such as the near approach of the Conference will dispel or resolve. Some of them are differences which will keep, and

which can be postponed till after the Congress. The Congress itself will swallow many of them up, and give an overwhelming exhibition of the unity of the profession, such as will best at once answer and convert those who would break it up into sections and cliques, or liberate any of its members from those great traditions which have been the distinction of the profession from the time of Hippocrates downwards.

There are, indeed, powerful attractions to draw members of the profession over to Washington in 1887. The road is not an untrodden one. Many of our brethren have already crossed the water, and they bring back but one report of the greatness of the land, and the hospitality and kindness of its people, and especially of our medical brethren. Besides this, we need not remind our readers of the fact that medical art and science are in a most active state across the Atlantic. The Americans set us an excellent example year after year of disregarding the sea and its sickness in search of knowledge, and to acquire the last hints of Europe in art or science. They come so freely that we are apt to think they are only learners, and not teachers; but no mistake could be greater. They are profoundly influencing both surgery and medicine, and our own foremost leaders would be the first to admit their indebtedness to American physicians and surgeons in respect of details, and of boldness, in the improvement of instruments, in the great operations of surgery, in the addition of new medicines, and of enterprise in the whole field of pathology and therapeutics. — *Lancet*.

THE *Lancet* has not taken up a wise line in reference to the Washington Congress. It has either been misinformed as to the facts and the importance of the unfortunate dispute now going on in America, or else it has wilfully shut its eyes to them. It is absurd, for instance, of the *Lancet* to attempt to minimize the differences which have caused the withdrawal from the Congress of almost every man of mark in America. The fact that nearly every medical journal of any repute in the United States has vigorously condemned the action of the American Medical Association, and given its warm support to the men who are contending for the freedom of the profession against the selfish designs of a clique, should in itself have induced the *Lancet* to give a little more attention to the question before taking the wrong side with such a light and careless heart. The sole fact that seems to weigh with the *Lancet* is that Dr. Flint has been appointed President of the Congress, or rather that his original appointment has been confirmed by the new Committee. Dr. Flint's is no doubt a powerful name to shelter one's self behind. He is incontestably one of the most eminent representatives of the profession in the United States, and it has been a source of profound sorrow to those who have felt constrained to withdraw from the Congress, that in doing so they have had to part company with him. But we cannot blind ourselves to the fact that Dr. Flint, eminent and honored as he is, has in the present instance allowed himself to be made the instrument of a minority. The part which Dr. Flint would take in this lamentable strife has been foreseen and discounted. The men of Boston, Philadelphia, and Baltimore who withdrew from the Congress knew that he would not follow them. The fact is that Dr. Flint is bound up with

the American Medical Association, and an honorable feeling of loyalty no doubt constrains him to accept its decisions, however much he may deplore them in his secret heart. — *Medical Times and Gazette*.

#### PARALYSIS OF THE BLADDER FROM THE USE OF CARBOLIC ACID.

CARTAZ, in the *Gazette méd. de Paris*, 1884, No. 42, reports interesting cases of vesical paralysis due to the use of carbolic acid in surgical dressings. This is one of the various toxic effects of the acid, and has been observed by the writer only twice, occurring in the first instance after irrigation of the uterus with a two per cent solution of carbolic acid after abortion. The paralysis disappeared on the substitution of corrosive sublimate as a disinfectant. The second instance was met with in the case of an aged woman with fracture of the neck of the femur. The dressings, which were daily changed, were treated with five per cent solution of carbolic acid. In two weeks there was an enormous distension of the bladder, and for forty-eight hours the woman had not urinated. By the catheter about a quart of dark brown urine was evacuated. In four days the paralysis disappeared, the carbolic solution having been replaced by boracic ointment. There appeared no reason to doubt that in each case the paralysis of the bladder was caused by the drug in question, as in both patients the urine had the color characteristic of carbolic acid poisoning, and the symptoms of paralysis in each case disappeared on abandoning the use of the drug. Only two similar cases are reported, and in these vesical paralysis resulted from drinking a concentrated solution of the acid. — *Centrabll. für Chirurgie*, March 28, 1885.

#### ASSAULTS BY GANJA-SMOKERS.

MURDEROUS assaults by individuals under the influence of Indian hemp have been somewhat frequent of late in Bombay. At the Bombay Police Court, towards the end of May, last, two cases of this nature came up for trial. In both cases the assailants were Mahomedans. In one case, the prisoner, Khuda Baksh, without provocation, struck with his fists a Parsee child, aged two and a half years, which was being carried along the street by an older girl. He there-afterwards seized the child by the legs and dashed its head on the ground. He was then seized by the passers-by, and, on being brought before the Magistrate, pleaded guilty, saying that he at the time was under the influence of ganja, and did not know what he was doing. As the child recovered from the concussion of the brain, the man was only sentenced to six months' rigorous imprisonment. In the second case, a Moghul, named Syed Hossain Ali Khan, while under the influence of ganja, was walking in the street with an open knife in his hand, when he made a thrust at another Moghul with the knife. The attacked individual, by stepping backwards, received only a comparatively superficial wound over the stomach. The assailant then fled through the bazaar like a maniac, brandishing the knife, and threatening to attack every one in his neighborhood. He was seized with much difficulty, and was sentenced to six months' rigorous imprisonment. A very large number of the inhabitants of this country are addicted to this form of in-

toxication, and the present low price of the drug allows of its being too readily procurable, so that further restrictions on its sale are certainly called for in order to lessen this source of bodily danger from the ganja-habitue, to which the public are constantly exposed. — *Indian Medical Gazette*.

#### Correspondence.

##### COCAINE IN CRACKED NIPPLES.

MR. EDITOR,—As it is the correct thing to use the muriate of cocaine for everything from corns to toothache, and as I have not seen it recommended as yet for fissured or eroded nipples of nursing women, I wish to report that I have found it to be a perfect anæsthetic in these cases. In three such cases a four per cent solution was applied with a small brush, in five minutes a second application was made and five minutes later two of the patients nursed directly from the nipple, the other using a nipple shield. All experienced a complete relief from pain. Furthermore it did not appear to hinder healing of the part. If time is any object a stronger solution should be used. Washing the nipple before the child nurses seems to make no difference to either mother or child.

1083 TREMONT STREET.

GEOR. C. MEYER.

##### ON THE INCOMPATIBILITY OF CHLORAL HYDRATE IN THE PRESENCE OF POTASSIUM BROMIDE AND ALCOHOL.

BOSTON, MASS., SEPT. 1, 1885.

MR. EDITOR,—In the July 23d number of the *JOURNAL*, Professor Markoe in a communication calls attention to an alleged incompatible prescription consisting of

"R Bromid Potass.	.....	℥ ss iiii.
Chloral Hydrat.	.....	℥ ss iiii.
Tr. Opil et Camph.	.....	℥ ss iiii.
Syr. Zingiber.	.....	℥ ss iiii.

Sig. One or two teaspoonfuls in half a wineglass of water every 2 to 6 hours. For sleep."

He says on putting this prescription up, a separation of it occurs into two layers, due, in his opinion, to the formation of chloral alcoholate, which is less soluble. He also cites in full three experiments to prove his supposition.

Now, I have repeated the three experiments cited, but do not get the separation into layers which he describes, but on the contrary, a perfect homogeneous mixture results, in each case. Under Ex. 2, he says: "After standing a short time the mixture separated into layers." I do not know what he calls a short time, but my mixture has been standing three days, and has not separated as yet.

Thinking that perhaps the method of putting up the prescription might vary the result, I repeated Ex. 2 by two different methods.

In the first, I dissolved the chloral in the alcohol and the potassium bromide in the water and syr. of ginger, and mixed the two solutions.

In the second, I dissolved the bromide of potassium and chloral together, in the syr. of ginger and water and then added the alcohol, and in both cases the result was a homogeneous mixture, as before stated.

To separate portions of these two mixtures I added a small amount of tr. opil Camph., but that did not affect the stability of the mixture. Showing that the other ingredients in the pargorie played no part in the alleged incompatibility.

I wish also to state that the drugs used by me were U. S. P. I cannot account for Professor Markoe's results, except that either he had not shaken his mixtures carefully or else drugs of a peculiar quality were used.

I would add that my results seem to be confirmed by statements in September number of the *Druggists' Circular*, Page 178, and in the *Pharmaceutische Rundschau*.

Yours respectfully, HENRY LUDWIG

CLINICAL NOTES OF PSORIASIS.<sup>1</sup>

BY F. B. GREENOUGH, M.D.

It is with no expectation of throwing any new light on so well-known and not uncommon a disease as psoriasis, that I venture to occupy the time of the meeting. The fact, however, of having had the opportunity of seeing quite a number of cases of this disease, 394, and of having endeavored to obtain such records of them as were obtainable, seemed to me to furnish data for some statistics, which might be of value, if for nothing else, with regard to the questions of sex, age, date of first appearance of the disease, evidence, either positive or negative, as to the history of an hereditary influence, etc.

Apart from the mere statistical information that can be obtained from these records, I have been much interested in seeing how far the cases seen conform to the description of the disease as given by the recognized authorities. In any large number of cases some anomalous ones must occur, and these are the ones that are more especially interesting from a diagnostic point of view. Inasmuch as the majority of the patients seen have been out-patients at the Boston Dispensary, the records necessarily cannot be anywhere near as complete, as they would be in the case-book of one's private practice. In fact, with the exception of the entry made at the time of the first visit, which gives the sex, age, the date of the first appearance of the disease, if any apparently reliable testimony on that point can be obtained, and also any hereditary influence or known absence of it, the data as to appearance, progress, and termination of the cases are entirely a matter of recollection.

These 394 cases of psoriasis occurred in a number of about 15,000 patients seen seeking advice for cutaneous disease. That is to say, the cases of psoriasis observed, were a little over two and one-half per cent of the cases of general skin disease seen. This is a larger proportion of frequency than usual: Hebra's statistics give the ratio of psoriasis to general disorders of the cutis, as one in sixty, or one and two-thirds per cent. Of these 394 cases, 205 patients were males, and 188 females. This gives a slight excess in favor of the male sex. With regard to the age of the cases when first seen, twenty-one were under ten years old. Four were four; one was five; five were six; two were seven; six were eight; and four were nine; in all twenty-one. Thirty-three were from ten to fifteen; forty-seven were from fifteen to twenty; one hundred and twenty-nine were from twenty to thirty; seventy-two were from thirty to forty; forty-two were from forty to fifty, and there were fifty cases that were fifty years of age and over; in all, three hundred and ninety-four. Forty-four cases when first seen gave decided testimony, or it was given for them, that they had not had any previous manifestation of the disease. Seven of these were under ten; that is, two were four; two were six; one was eight; and two were nine; five were from ten to fifteen; six from fifteen to twenty; fourteen from twenty to thirty; six from thirty to forty; five from forty to fifty, and one over fifty.

In one hundred and seven cases the age at which they were first attacked by the disease, was reported in

a way to warrant accepting it as probably correct. They were as follows: under ten there were thirteen; that is, one was three; two were four; two were five; one was six; three were seven; four were eight; in all thirteen. From ten to fifteen there were thirty; from fifteen to twenty there were fifteen; from twenty to thirty there were twenty-six; from thirty to forty there were thirteen; from forty to fifty there were five; and over fifty there were five, which five cases were respectively fifty, fifty, fifty-two, sixty and sixty-seven.

Taking these one hundred and fifty-one cases, (forty-four seen and one hundred and seven reported) where the date of the patient's age when first affected by psoriasis could be got, we have: a number of cases, 151; under ten there were twenty; from ten to fifteen there were thirty-five; from fifteen to twenty there were twenty-one; from twenty to thirty there were forty; making ninety-six; from thirty to forty there were nineteen; from forty to fifty there were ten; over fifty there were six; in all, one hundred and fifty-one.

It will be noticed that out of these 151 cases, ninety-six were first affected with psoriasis between the ages of ten and forty, which is what we should expect: that is to say, that a large proportion of the whole number should come between those ages, but twenty cases out of 151, occurring in individuals under ten years of age is certainly contrary to the teaching of the books, and that there should be six cases who were attacked by the disease for the first time, after passing their fiftieth year, is still more extraordinary. In ninety-seven cases I was able to get what seemed to me to be sufficient evidence as to the existence, or the reverse, of an hereditary influence. I have only taken those where the intelligence of the patients and the circumstances of their lives made it seem probable that their testimony on the subject was reliable. In thirty-one cases I got a history of the probable existence of psoriasis in some immediate member of the family, and in sixty-six cases there was a denial of any such disease, from individuals who had lived at home, or would be likely to have known if any of their near relations had been afflicted in the same way that they were. The fact that very nearly one-third of the number of patients from whom any definite evidence on the subject could be obtained, gave an account of the disease having manifested itself in their family circle, would tend to show that hereditary influence played more of a rôle in the causation of psoriasis than is generally thought. It is true that thirty-one cases out of three hundred and ninety-four is not a large proportion, but on the other hand it must be remembered that the great majority of these cases, being seen as out-patients in a public service, belong to a class in which family ties are not long kept up, and many of them being of foreign birth, know little or nothing about their family. In fact in only ninety-seven instances could any information which seemed reliable, be obtained, and of these, very nearly a third reported the existence of an hereditary influence. The term hereditary influence is used in its broadest sense, as I have included under it the cases where the disease was reported as having been known to exist in uncles, aunts, brothers and sisters, and in some cases in progeny. Perhaps a family tendency to the disease would be a more strictly appropriate term.

With regard to the general health of these cases, I should say that on the whole, Hebra's statement that

<sup>1</sup> Read at the annual meeting of the American Dermatological Association, August 26, 1883.

the subjects of psoriasis are apt to be strong, robust and hearty, holds good; perhaps to a lesser extent in the female than in the male sex. Whether this difference between the sexes is any greater than can be explained by the fact that the women of the lower and middle classes, are as a rule, less robust than their laboring, outdoor-working husbands, I cannot say. I remember few of these cases of psoriasis that showed great general debility and poor condition, whereas, on the other hand, quite a large proportion of them exhibited every evidence of robust and blooming health, having large muscles, and being rosy, perhaps with a tendency to rather more adipose tissue than is consistent with our idea of perfect condition.

The conventional type of the butcher, or market-stall man, represents very well the physical condition of quite a number of them. In many others, however, the general health was neither markedly good nor the reverse. The localities of preference of the eruption in the cases seen, have proved very uniformly to be those described by the authors. In those cases where the eruption was at all fully developed, almost constantly efflorescences would be found about the elbows and knees, and occupying the extensor side of the limbs much more than the flexor. This fact is one of the most important helps we have in diagnosis. There are of course exceptional cases, of one class of which I have seen several instances, having several spots, or one large patch of eruption confined entirely to the legs below the knees, without any sign of manifestation elsewhere. One of the most interesting of the cases seen was that of a negro. The eruption was of the nummular form, consisting of several circular patches, from the size of a quarter to that of a silver dollar, slightly raised above the surface, and giving to the touch the feeling of infiltration. The color of these patches was perhaps slightly darker than that of the surrounding, healthy skin, but very slightly so, and this was the only evidence of hyperæmia. The patches were covered with heavy epithelial scales, which instead of the characteristic pearly whiteness, showed a dirty grayish tint, and when removed and held up to the light, even to the naked eye, showed numerous very fine points of pigment, as though they had been powdered with a very fine, dark gray pepper. Unfortunately this patient, like many others, disappeared, and was only seen twice. It is chiefly with reference to diagnosis, and more especially with regard to points of differential diagnosis, that the observation of a large number of cases can be made of value. While a fully developed and typical case of psoriasis is one of the most well marked and easily distinguished of skin diseases, there are nevertheless cases where the diagnosis is by no means so easy, either because the case is anomalous or from the fact of the eruption having been affected by treatment, or on account of its having, when first seen, already begun to change in appearance from the process of involution having begun. Again where a large number of cases are seen, some will be found that are complicated by the coexistence of other cutaneous disorders, from which of course a patient is not exempted by the mere fact of his having psoriasis. The eruptions which most resemble, and at times are not easy to distinguish from, psoriasis, are those which are symptomatic of constitutional syphilis. My experience has been that quite a fair proportion of cases of psoriasis are mistaken for, and treated as, syphilis. I remember one case of a respectable middle-aged woman

who showed a perfectly typical case of psoriasis, with a history of its having first appeared before the age of puberty, and of having been affected by it off and on ever since, saying that she would follow out any treatment that I ordered, but she hoped that I would not give her mercury, as she had been salivated six times without any improvement in the disease. One of the most common regions for the manifestation of psoriasis is the scalp, and it is also a place where the diagnosis is sometimes difficult. The first appearance of the eruption in this situation is very much the same as that which is found as one of the earliest, and not unfrequently the first, symptoms of secondary syphilis. In both cases the efflorescence consists of a small crust or scab, raised above the surface, generally on the top of the scalp, or on the temporal regions, which generally is first discovered by the patient from the fact of his comb catching on it. As far as one can judge by simple inspection there is very little difference between them, but while the crust of a commencing patch of psoriasis is entirely epithelial, which when picked off will show a few points hardly larger than a pin's point from which blood oozes, the scab due to syphilis is the result of a small pustule, and when removed will show a drop of moisture, or at least a raw surface as a base.

There is one peculiarity in the eruption of psoriasis on the hairy scalp, not only in its first appearance as small separate points of epithelial crusts, but also when it has increased into large patches, even to the extent of involving the whole of the region covered by hair, and that is that the hyperæmia, which is always noticed in patches on the skin elsewhere, cannot be seen. That is to say, psoriasis on the hairy scalp shows more or less epithelial scales, but no redness. In this respect it is analogous to the efflorescence of the tinea trichophytina, which on the scalp simply appears as a dirty, grayish scurfy spot, while on the integument elsewhere we have a decided redness of the circular patches affected. Whether the congestion of the affected part of the scalp does not exist, or whether the hair prevents its being appreciated, I cannot say, but its absence is not due to the locality, for in cases of patients who have become bald who have psoriasis, the redness of the patches on the scalp is just as marked as anywhere else. One quite characteristic symptom of psoriasis of the scalp, is the existence of a band of hyperæmia from three-eighths to one-half an inch in breadth, running along the forehead contiguous to the margin of the growth of the hair. The skin here is red and shiny, but I have never seen heavy scales on it. This band of hyperæmia is typical of psoriasis and is to be considered in questions of differential diagnosis between psoriasis of the scalp and eczema capitis. This differential diagnosis is at times rather puzzling, and I have seen a few cases where I was decidedly in doubt as to whether I had to do with a case of psoriasis of the scalp, eczema capitis, or favus. The thing to be remembered is, that in psoriasis the crusts and scales are simply epithelial, whereas in even chronic eczema some evidence of dried serum or pus is likely to be found, or at least, history of its previous existence is obtained. Eczema, when affecting the whole scalp, is very apt to extend to the ears, and I never have found any enlargement of the post-cervical glands in cases of psoriasis, whereas in eczema of the scalp it is quite common. The line of hyperæmia on the forehead, which I have referred to, is never seen in eczema, and lastly, it would be rare to have a

case of eczema capitis in which you could not get a history of some previous acute attack, as shown by the exudation of serum matting and stiffening up the hair. With regard to favus, the patient would have to be quite young, the crusts would be more solid and like mortar, which when picked off would leave a granular raw base. Evidence of destruction of the hair follicles, as shown by partially bald patches would be seen, and very likely the yellowish cup-like appearance characteristic of favus could be determined. The microscope would, of course, settle the diagnosis. I have never been able to satisfy myself that psoriasis of the scalp, even when affecting the whole of it, caused any permanent loss of hair. This seems extraordinary, when we think of the very decided damage which we see resulting from what seems to be a much less serious abnormal condition of the scalp in cases of alopecia furfuracea. Nevertheless, I think I can say, having carefully watched some cases in private practice, that the hair is not affected either in quantity or quality. In one case the patient, a lady, thought that a rather premature tendency to grayness was due either to the disease, or to the local remedies used, but I doubt it. Before leaving the scalp I would say that I have often found in doubtful cases that a question as to whether the patients had not at times been troubled with a very decided amount of dandruff, would, if they had had psoriasis, be answered very promptly in the affirmative. On the general integument a squamous syphilide is one of the eruptions that is most likely to show points of resemblance to a case of psoriasis. In both, the serpiginous outline of the efflorescence is apt to be found, owing to the same cause, that is, the extension and coalescing of circular patches. In this connection the regions on which the eruption is most thickly distributed is a very important point, as while psoriasis is found to affect the extensor side of the arms and legs, the syphilides are much more apt to be developed on the side of the flexors. There is, however, a decided difference in the first appearance of the two eruptions. Although psoriasis is universally described as starting as a small raised spot of congestion covered with an epithelial scale, my observation is that it invariably begins as a very minute point of simple hyperæmia. Theoretically every efflorescence, whether macular, papular, squamous, vesicular, or pustular, must begin by hyperæmia, but I mean that in psoriasis, this condition of simple congestion lasts for several days as such. In the case of a macular syphilide it is different; in twenty-four, or even twelve hours from the time when the cutis was seen to be normal, a crop of macules from the size of a small shot, to that of a little fingernail, will appear. It is, of course, possible that these spots may start as very minute specks of congestion, but I have never seen them in that stage, whereas, I have time after time seen the gradual development of a patch of psoriasis from an almost infinitesimal point of congestion. In the fading out of these eruptions there is even a more marked difference. In a syphilide, as the congestion passes off, a decided pigmentary stain will be seen, which remains for some time. In the case of a patch of psoriasis no pigmentation at all remains. The reason of this is that the nature of the eruption is such, that the epithelial layer, in which the pigment in cases of chronic hyperæmia is deposited, is being blown off and exfoliated as fast as it is formed. That this is the case is shown very well in cases where chrysorolin is

used as a remedial agent. After applying it for a few days it will be noticed that while the healthy skin around the patch of psoriasis to which it is being applied will be stained and dirty looking, the patch itself will look like clean healthy cuticle, and as long as that is the case the morbid process has not been overcome. That is to say, the remedy must be persisted in, until the stain is as marked on the spot treated as on the surrounding skin. It is not, however, the remaining pigmentation alone that is characteristic of a fading syphilide, but in many cases that pigmentation shows a decided character, which is not seen in any other eruption, at least I never have seen it. As the hyperæmia of a syphilide macule ceases we find a certain amount of pigment deposited on the extent of surface formerly congested. The hyperæmia will be found to continue, however, in a series of points, which correspond to the mouths of follicles, and when it disappears entirely these points will be seen to be accentuated, or more darkly pigmented than the intervening surface, which gives a very characteristic punctated appearance to the skin, which is only seen after a syphilide eruption. It is, however, the later or squamous type of syphilide which is especially liable to be confounded with psoriasis. A fully developed syphilide of a squamous character, is very apt to show points where there is more or less tendency to breaking down, or ulceration, in which case the crusts or scabs would be very different from the dry, shiny epithelial scales exfoliated from a patch of psoriasis. It must, however, be remembered that in some cases of psoriasis there is sufficient itching to cause scratching and tearing the skin, as a result of which scab crusts may be found, and also that the coexistence of scabies, or the presence of pediculi vestimentorum may produce the same result. These crusts, however, will generally contain dried blood as well as pus and serum, and the evidence of scratching can be recognized by the linear lesions resulting. Excepting as a result of actual injury to the cutis, by the fingernails or other sources of irritation, the scales found on the patches of psoriasis consist of simple epithelium, whereas those covering the efflorescence of a syphilide eruption will be formed by dried pus and serum. The amount of pruritus that accompanies an outbreak of psoriasis varies very much in different cases, and its intensity does not seem to depend upon any special characteristic of the eruption, either as to its stage of development, its form of distribution, or the amount of surface of the integument involved. In some cases it is most marked at the time of the first appearance of the disease, and ceases as it develops; in others, it reaches its maximum of intensity when the patches are fully developed and covered by heavy epithelial crusts. I should say that it was rather an exception to have itching a prominent symptom, but in some cases it certainly is one of the most distressing ones for the patient. There are many cases of eczema squamosum in which if a piece of paper, with a hole cut in it, say an inch or two in diameter, were placed over a patch of efflorescence, the surface seen could hardly be differentiated from psoriasis, and *vice versa*. Fortunately, we are not confined to examining any one part of the integument, and when the whole of the eruption is seen, the distribution, the more sharply drawn margin in the case of psoriasis, the existence somewhere of heavy characteristic scales, if psoriasis, or evidence of dried serum or pus, if eczema,

will help our diagnosis. I have, however, seen a few cases where the eruption was confined to the anterior part of the lower leg, and consisted of several small, or one large, patch of shiny red infiltration, without any scales, crusts, or scabs, in which no cutaneous abnormal manifestations elsewhere were to be seen, and no light could be obtained by any previous history, that have been quite puzzling in the way of diagnosis. I remember one of these cases, the diagnosis of which (between psoriasis and eczema) I have never felt sure of. In one instance, I made the mistake of taking a commencing case of psoriasis to be one of seborrhea. The patient was a young woman, rather anemic, who showed two circular patches over the sternum covered with very thin fine scales, of a dirty yellow color. Through these scales the base of the patches was seen to be very slightly congested. They were not raised above the surface of the skin, and had, by report, existed for some little time slowly increasing in diameter. It was only after having seen the patient three or four times that a crop of similar patches appearing on the trunk and limbs convinced me of my error. I have had the case under observation since, seeing her through two or three relapses. I have noticed in other cases, occurring in female subjects, the same thin and almost powdery character of the scales covering a patch of psoriasis, and I am inclined to think, though I will not state it as a fact, that in this form of the eruption the scales can be removed without being followed by the characteristic oozing of minute points of blood, which shows that the papillae have been laid bare.

In another case I mistook the first appearance of psoriasis for tinea trichophytina. This case was seen some time ago, and I think that the youth of the patient, a little girl, four years old, had more influence on my judgment in excluding psoriasis than it would now have. The eruption, however, certainly did resemble that of tinea very closely. It consisted of a few small circular patches, confined to the breast and shoulders, slightly raised above the surface, the slight amount of scales noticed being decidedly more evident on the margin than elsewhere, and accompanied with a marked pruritus. In this case, as in the previous one, a more general outbreak of the eruption showed the true nature of the disease. I have never seen any eruption on the palms of the hands or soles of the feet that in any way resembled psoriasis, with the exception, of course, of eczema, that was undoubtedly syphilitic. This is a point on which I can speak most decidedly, of course merely as far as my own observation goes. And equally decidedly can I say that I have never seen any lesions of the buccal mucous membrane, accompanying, or in any way connected with, or due to, psoriasis.

With regard to the influence of temperature or climate on the disease, I have not been able to form any opinion. Some patients state that they are always better in the summer season, and about the same number say that cold weather seems to improve their condition.

With regard to treatment, my experience has undoubtedly been the same as that of every other practitioner, that is, that some cases do very well, and others do not do at all well. We most certainly know of no specific, and of the many local applications that have been tried that one which will produce a marked improvement in one case will prove absolutely inert in

another. The great majority of the cases that have come under my observation being out-patients visiting a charitable public service, the opportunity for carrying out a protracted course of treatment is very slight, as those that do not get relief will go to some other institution. One can hardly expect a man who has been hard at manual labor all day, or a woman, who has a family of children to take care of, to give up from a quarter to half an hour before getting the rest they so much need, to rubbing in ointments, etc., to say nothing of the mess and dirt it makes.

To get rid of a decided case of psoriasis is most important for the patient, as this cutaneous lesion is almost universally looked upon as showing some taint which would render the subject unfit for intercourse with other people. Even when the result of treatment is most successful the patient must be told of the not only possibility, but great probability, of a future relapse.

On the whole I have found the preparations of a tarry nature, especially the oil of cade, the most efficacious in the treatment of psoriasis. I have used them very largely and have never had a case of the black urine, and other toxic symptoms that are sometimes called forth by these agents. I always make it a principle in a new case, not to have the remedy applied over large surfaces at first. In some cases great comfort can be obtained by simply using some emollient to soften the crusts, especially those on or near the large joints, which in some cases make every motion almost a torture. Cod liver oil is one of the best applications for this purpose, and as a matter of routine practice I use a mixture of equal parts of it and the oil of cade. In addition to softening the scales, their removal is important. This can be done by washing with any soap, the *sapo viridis* being one of the most efficacious in cases where it is not too irritating. In private practice where the cod liver oil is objected to, the oil of cade can be diluted with olive oil, glycerine, or some of the petroleum products. Oil of cade, glycerine, and rectified spirit makes a very good application, when the greasiness of the remedy used is objected to. I order the tarry preparation to be applied at bedtime, with a piece of flannel or a brush, and in the morning to have the places to which it has been applied thoroughly washed with German soap, or the *spiritus kaliumis*, or if these are too strong, simple castile soap.

On the face or hands, where the patient objects to using tar, the white precipitate ointment in some cases has acted very well. In chrysarobin we have undoubtedly a very powerful agent in many cases. It is used generally by patients under protest, as it absolutely ruins any clothing or bed-linen that it may come in contact with. I have also found that it is not safe to use it on the face or scalp, even when ordered in quite a small proportion to the vehicle employed, as it is apt to start up quite a violent dermatitis. When employed on the trunk or limbs it should be remembered that its use should be persisted in until the staining of the patch being treated, in the same way as the surrounding tissue, shows that the exfoliation of epithelium has ceased. When the scalp is the seat of the disease the result of treatment is generally very marked. An application of the oil of cade, diluted according to the sensitiveness of the patient, with cod liver, olive, or other oil, at night, followed by a thorough shampooing the next day, with the tr. kaliumis and the

use of a stiff brush to remove the scales that have been loosened up, will give great comfort to the patient. There can be no doubt but what the internal administration of arsenic has a marked effect in some cases; in others it seems to be absolutely inert. I have not found any benefit from increasing the dose, and in cases where a moderate amount does not produce any effect, I stop its administration.

Even in those cases where treatment is most successful the patient must be warned as to the likelihood of a relapse. I have, however, some half-dozen cases under pretty constant observation and treatment, in which, by taking hold as soon as any signs of a relapse appear, the disease has been pretty well held in check for some years.

In conclusion, I would say, that while I am fully aware that the deductions drawn from the points I have touched upon, must, in a great measure, be repetitions of well-known facts, I have ventured to hope that, even if only as confirmation of accepted ideas, or the reverse, by personal observations, my notes may not be absolutely useless.

#### THE APPLICATION OF ANTISEPTIC PRINCIPLES TO GENTO-URINARY SURGERY.

BY A. T. CABOT, A.M., M.D.

IN the discussion upon "Catheter Fever" which prevailed in the past year throughout Great Britain, it was generally acknowledged that a considerable proportion of the cases included under this term are of septic origin, and are due to the introduction of germs upon instruments used. This view found especial support in Edinburgh, where Professor Chiene, Dr. Wyllie, and Professor Amundale advocated it most strongly.

Certainly, as the habit of making thorough autopsies becomes more general, many cases of fatal issue after instrumentation, which would formerly have been referred to reflex or other nervous influences, are found to be septic in character.

It is not proposed to discuss here the various causes of "Catheter fever," but to confine our attention to the cases of urinary disease which are generally admitted to be of septic origin.

These cases may be divided into four classes:

*First:* They may be of a distinctly pyæmic character with metastatic inflammations in the joints, internal viscera and other parts of the body, frequently accompanied by chills.

*Secondly:* They may present the familiar symptoms of septicæmia, with chills, high temperature and rapidly fatal course, with the post mortem appearance of a granular degeneration (cloudy swelling), of the various internal organs.

*Thirdly:* In other cases with grave constitutional disturbance leading rapidly to a fatal issue, autopsy may reveal diphtheritic ulcerations of the urethra, bladder, ureters and even of the pelvis and substance of the kidneys.

The cases included in these first three classes are most commonly ones in which there has been some operation involving a wound; such as the division or division of a stricture, a difficult catheterization or a lithotomy in which abrasion of the mucous membrane has occurred.

The *fourth* class includes those cases, less serious,

but far more common, in which a general cystitis is set up by the introduction of ferments upon dirty instruments.

Fortunately the neglect of absolute cleanliness does not always result in harm, and this is so, not because the germs are harmless, but because healthy tissues and especially epithelial surfaces have great power to resist septic influences.

If a bladder is in good condition and completely empties itself at every urination, the introduction of a few germs is not likely to cause trouble, for before they can multiply to any extent and produce a marked degree of fermentation, the urine in which they are propagating is thrown out and the danger is averted.

If, however, owing to any obstruction or through loss of power, the bladder does not completely void the urine, it then cannot free itself of any germs that may find their way into it, so that these ferments when once introduced have ample time to act upon the residual urine and to produce changes in it. And the irritating products of this fermentation soon cause inflammation of the bladder walls.

Unfortunately, these cases in which the bladder habitually contains residual urine are just the ones in which the frequent use of a catheter is required, so that it often happens that germs are introduced into stagnant urine and many cases of cystitis are the unfortunate result. A result all the more common from the fact that in these cases the catheterization and care of the instruments must often be left to the patient himself who cannot understand the importance of the care necessary for thorough asepticism.

Professor Chiene, in a recent discussion in the Edinburgh Medico-Chirurgical Society, enumerated the following ways in which septic matter may reach the bladder:

*First:* It may be introduced upon an impure instrument.

*Secondly:* It may be carried in also by air rushing through a catheter.

*Thirdly:* It may enter by passing along an inflamed urethra, which has been irritated by a prolonged use of instruments.

*Fourthly:* Organisms may pass between the instrument and the wall of the urethra when a catheter is tied in.

Such are the dangers! To guard against them is possible but not easy.

Urethral and bladder instruments are complicated and hard to keep clean; even a catheter which is in frequent use can be rubbed and thoroughly cleansed only upon the outside, while the inner surface of the tube, constantly traversed by urine, which is often foul and loaded with mucus, cannot be reached except by irrigation. Further, as catheters are now generally made, there is, below the eye, in the point of the instrument, a pocket (Fig. 1, a.) in which impurities of every sort collect, and from which it is almost impossible to dislodge them, as they are in an eddy out of the current when the catheter is flushed by a stream of water thrown through it.

In a silver, or other metallic instrument, this pocket may be easily obliterated (Fig. 1, b.) so that the eye is at the end of the tube, and a stream of water running through reaches every part with full force.

Soft rubber catheters should also be made in this way, and in some of those that I have recently obtained, made under the Jacques patent, this pocket is very

much reduced in size as represented in Figure 1, c. The Davidson Rubber Company make a soft catheter with the opening at the extreme end (Fig. 1, d.) and with a view to cleanliness, this is a most excellent arrangement; but unfortunately it renders them more difficult

Fig. 1.

of introduction and more irritating to the urethra than the ordinary form, so that their advantages are more than counterbalanced. This company have also endeavored to make a soft catheter with a point like that in Figure 1, b, but the technical difficulties in the working of the rubber have thus far prevented their success.

Webbing catheters, both French and English, have this same disadvantage of form of which we have been speaking, and have the additional fault that their surface, whether of oil or rubber, is easily cracked, and is therefore difficult to keep antiseptically clean. An old instrument of this kind is always a source of danger.

#### METHODS OF DISINFECTION.

Thorough disinfection of intricate or hollow metallic instruments can be accomplished by prolonged boiling, which not only raises them to a temperature at which the germs cannot survive, but also dissolves away oily impurities in crevices which would not be reached by the most thorough scrubbing. If the instruments are plunged at once into boiling water albuminous particles are precipitated by the heat and are then difficult to remove. It is a better plan, therefore, to put them first to soak in cold water which is then gradually raised to the boiling point, and this should be maintained for at least a half an hour.

As the disinfection by heat requires some outlay of time and trouble, most surgeons prefer the easier but less efficient disinfection by antiseptic washing and scrubbing. This should be thoroughly done immediately after use, while the impurities (urine, mucus, blood, etc.) are still moist and easily washed away.

Every instrument should also be rinsed off in an antiseptic solution immediately before it is used, even when it has been previously boiled or thoroughly washed. This is to remove any dust that may have settled upon it while laid away.

Rubber and gum elastic catheters after careful cleansing should be subjected to long soaking in antiseptic solutions, especially when they are in constant use.

The best solutions for antiseptic washing are, carbolic acid one part to twenty parts of water, corrosive sublimate, one part to one thousand parts of water, liquor soda chlorinate, one part to ten or fifteen parts of water. Phenyl, too, in the proportion of one to

fifty or one hundred is excellent for use upon metallic instruments, but acts injuriously upon rubber.

Chlorinated soda has the advantage that it saponifies and removes fats, but both it and corrosive sublimate have the disadvantage of corroding metals.

The five per cent carbolic solution, therefore, so familiar to surgeons, remains the best antiseptic wash for these as for other instruments.

It is further to be remembered, that an instrument, perfectly clean itself may carry on into the bladder impurities which it finds about the meatus or in the urethra. This is especially liable to occur in the catheterization of women, as in them the urethral orifice is often bathed in lochial or leucorrhoeal discharges, which besmear the catheter at the time of its introduction.

To guard against this danger, the parts about the meatus urinarius should be carefully cleansed before an instrument is introduced, and if a urethritis exists, a preliminary irrigation of the canal by removing the discharge, will lessen the danger of carrying germs on to the deeper parts.

The danger from the introduction of microorganisms with air which finds its way through a catheter into the bladder is probably not very great; still it is important to avoid even the slight amount of risk which would come from this source.

With a soft catheter the end can easily be submerged in the urine as it flows, and thus air can be prevented from entering. With a stiff instrument it is not so easy to prevent it unless the catheter is withdrawn while the urine is still flowing. Especial care should be taken, if pressure is made above the pubes to hasten the flow of urine, that before such pressure is removed the catheter is stopped or withdrawn, as otherwise, air will be directly aspirated into the bladder.

#### CHOICE OF A LUBRICANT.

It is, of course, a most necessary precaution to choose as a lubricant for urethral instruments a substance which is at least aseptic, and if possible is somewhat antiseptic.

In many cases, no doubt, a well-selected lubricant so coats the instrument that even if there are germs upon it they are covered up and do not come in contact with the tissues or fluids and so fail to do harm.

Owing to the extreme sensitiveness of the urethral mucous membrane, the antiseptic chosen must be as unirritating as possible.

Carbolic oil which has been much used for this purpose will set up a urethritis in some patients and is, as Koch has demonstrated, of feeble antiseptic power.

For some time I have been using a mixture of eucalyptus oil with olive oil, vaseline, or castor oil, in the proportion of one part of eucalyptus oil to sixteen parts of the vehicle, and have found these mixtures to remain fresh and sweet for a long time, and to be unirritating to the urethra.

Castor oil has some advantages over any of the other oily preparations. Owing to its clinging character it adheres to the instruments until they reach the deep parts of the urethra, and it also does not produce the changes in soft rubber catheters which are often so troublesome when olive oil or vaseline are used. The two latter soon cause a rubber catheter to swell and become soft, whereas a long immersion in castor oil produces but little change.

Glycerine is a moderately good aseptic lubricant,

and as it is soluble in water it is especially useful when some drug is to be applied in solution to the urethra. An oily preparation under these circumstances would coat the mucous membrane, and so render the injection less efficient.

The third danger that Professor Chiene speaks of, namely, "that the bacteria will pass along an inflamed urethra which has been irritated by a prolonged use of instruments," can be greatly lessened by care in the selection and use of instruments and lubricants.

If a proctitis of this sort appears, the passage of instruments should be stopped if possible, and mild, astringent injections will then usually bring about a speedy cure.

When a catheter is tied into the bladder it almost always causes a urethritis, and this inflammation may take on a septic character. To afford as much protection as possible against this course of things, the urethra should be thoroughly washed out whenever the catheter is changed, and the penis and catheter, after careful cleansing may be sprinkled with iodoform powder and closely enveloped in salicylic cotton. In order to prevent any leakage of urine along the side of the catheter it is important to keep the bladder empty, and so to prevent any pressure from behind. This is best done by attaching a rubber tube to the catheter and dropping it over the side of the bed into a bottle, where its end may be submerged in an antiseptic solution into which the urine constantly escapes, being drawn out of the bladder by the syphon action of this tube.

#### IRRIGATION.

Thus far we have spoken of prophylactic measures. Suppose, however, that fermentation has reached the bladder and that the urine is foul, alkaline and loaded with bacteria; how can this state of things be best remedied?

The use of antiseptic irrigation occurs to every one, and could we inject at once a strong antiseptic solution and so destroy the germs present, the treatment of these cases would be comparatively easy. Unfortunately, however, the bladder will not tolerate these strong solutions; in fact, there is no mixture which can be used freely and safely within the bladder that is actively germicidal. The strongest solutions that can be properly injected are only capable of retarding putrefaction, not of stopping it. Although we cannot, in this way, at once attack and put an end to fermentation, we can do much to mitigate and remove it.

If we recall the conditions that bring about putrefaction in the bladder, we shall remember them to be first, the introduction of germs, and second, stagnation of urine. And we know that when there is no residual urine the occurrence of fermentation is very uncommon, because even when germs are introduced they are thoroughly voided before they have time to do harm.

If following this hint, we systematically draw off all residual urine once or twice a day, we shall, in a certain proportion of cases accomplish a cure by this means alone. For the bladder being relieved of its habitual distension will sometimes recover its tone, will thoroughly empty itself at each urination, and so will free itself of the fermenting urine.

As an aid to systematic catheterization, irrigation is of the greatest importance. By it we are able to wash out the dregs of fermenting material so that the

fresh urine as it comes from the kidneys is not so quickly hurried into putrefaction. This change may be still further delayed if a small quantity of the antiseptic be left in the bladder after the irrigation.

We are to look upon injections, therefore, as a means of removing septic matter rather than of *destroying* it; and it may be often found that astringent or soothing injections act better than antiseptic ones, their effect upon the bladder wall in allaying inflammation and checking suppurative being of importance.

The following are some of the more common and useful mixtures for antiseptic irrigation:—

A one-eighth to one-fourth per cent solution of carbolic acid is useful as a simple cleansing solution.

Borax (borograte of soda) in a three to four per cent solution is an excellent injection and its soothing properties make it especially valuable in irritable bladders.

Corrosive sublimate may be used in exceedingly dilute solutions (1-200 per cent) when the fecor of the urine is not removed by some of the milder injections.

When a combined antiseptic and astringent effect is desired, permanganate of potash (one-tenth to three-tenth per cent solution) may be employed.

Utzmann recommends resorcin (three to five per cent solution), or nitrite of amyl (two or three drops to four ounces) to obviate the fecor of the urine.

Besides these few mixtures which are mentioned because they are especially useful in overcoming a putrid condition of the urine, there are a host of other irrigating fluids which owe their beneficial effects to their stimulating or astringent actions upon the mucous membrane of the bladder.

The method of making injections varies greatly with different surgeons.

Sir Henry Thompson advises very cautious and gentle measures and thinks that one should "never under any circumstances throw in more than two ounces; and even this quantity for efficient washing is better avoided."

Dr. Utzmann, on the other hand, recognizing the importance of mechanically removing the fermenting material (mucus, etc.) which often clings tenaciously to the bladder wall, advises forcible injections with a hand syringe, for the purpose of detaching it.

Professor Guyon also recommends injecting the bladder by short, sharp strokes of the syringe, and immediately allowing it to flow out again before the sediment which has been stirred up has time to settle. He adds a warning against injecting more than a small quantity in this way, as the bladder, though not sensitive to contact, is very sensitive to distension.

He afterwards says that the same result (that is, thorough cleansing), is arrived at by filling the bladder slowly with as much liquid as it will contain, and then allowing it to escape.

In very irritable bladders, great gentleness must unquestionably be used, and care must be taken not to throw in more than the bladder easily tolerates. If in such a case, the fluid is thrown in rapidly, contractions are excited which eject what has been introduced, and render further irrigation impossible. For such cases, Sir H. Thompson's rule, that not more than two ounces shall be injected at a time, is most applicable.

On the other hand, many bladders are quite insensitive, and do not resent the more active measures recommended by Professors Guyon and Utzmann, when skillfully carried out.

There are certain reasons, however, which to my

mind makes this somewhat rough use of the hand syringe, as recommended by these authorities, unwise.

*First:* the injection is liable, even in skilled hands, to be carried too far, and to irritate the bladder by sudden distension, thus counteracting the otherwise good effects of the irrigation.

*Secondly:* if, in endeavoring to avoid this danger, we inject but little fluid at a time, we shall often accomplish the cleansing of but a small portion of the vesical wall; for those bladders to which irrigation is necessary are not seldom voluminous and much folded upon themselves.

*Thirdly:* a hand syringe is a complicated instrument, hard to keep clean and almost impossible to make clean if it once becomes dirty. It should, therefore, so far as possible, be excluded from the armamentarium of the antiseptic surgeon.

In view of these difficulties, I gave up years ago, the use of the hand syringe in irrigation of the bladder, and adopted the apparatus that I now use.

It consists of a clear glass bottle and a piece of rubber tubing about four feet in length, with a little piece of glass tubing at one end, drawn out to a nozzle that will fit into the catheter. The injection fluid is mixed in the bottle and the rubber tube is then arranged as a siphon to draw it out and convey it to the bladder.

We have in this arrangement, no valves to get out of order and to collect dirt. The tube can be readily flushed by attaching it to a faucet, and the bottle is easily washed after each use. As it is of clear glass, we can see when it is dirty, and also while it is in use, we can watch the fall of the fluid in it, and so know the exact amount which has entered the bladder. All of these are practical advantages, and the cheapness of the apparatus is another recommendation.

The force of the current is regulated by adjusting the height of the bottle above the bladder, and its flow is so steady and free from jerks that it does not excite contractions, and the bladder can be thoroughly distended by it. Great benefit follows from this complete distension, as all of the folds are eradicated and every part of the bladder wall is reached by the medicated solution.

In a case recently under observation, it required thirteen ounces of fluid to fill the bladder so as to cause the least sensation of fullness, and a few injections upon this plan entirely relieved a cystitis, which had not yielded to smaller injections with a Thompson's bag.

Some surgeons, when using a fountain syringe for bladder irrigation, attach to the tube a two-way cock or other contrivance, which enables them to reverse the current into and out of the bladder without removing the nozzle from the catheter.

This seems to me but a slight saving in the matter of convenience, and it is objectionable in that it introduces a part, which, while not necessary, is extremely hard to keep antiseptically clean.

Another use for these irrigation fluids is in the Litheolapex pump. It is a precaution of manifest utility to select for this most thorough washing of the bladder, a solution which shall at least be aseptic.

The antiseptic which is chosen for this purpose should be added to the water a considerable time before the solution is to be used, in order that it may have time to sterilize the fluid. This object is still further assisted if boiled water is used in the mixture.

#### DRESSING OF WOUNDS OF THE URETHRA OR BLADDER.

Lastly, we come to speak of the proper treatment of wounds penetrating the urethra or bladder. These may be the result of injury, but are more commonly caused by operations (cystotomy, urethrotomy, etc.)

The instruments used in these operations should be disinfected with as much care as for use on any other part of the body; and this should be insisted upon even when the urine is foul and ammoniacal.

To suppose that when the urine is putrid, antiseptic precautions are thrown away, is a common mistake, which should not be made by any one who believes in the separate and individual character of the organisms of the various wound fevers and septic processes.

Because the cystotomy wound is exposed to the organisms of putrefaction, it is not therefore proper to leave it open to the entry of the germs of erysipelas, pyæmia, and diphtheria. On the contrary, it should be protected from infection by every precaution before and during operation, and dressings should be applied to afford as much protection as possible afterwards.

The constant escape of the urine renders this problem of dressings a difficult one. Most antiseptic substances are quickly dissolved and washed away, leaving the wound unprotected.

Fortunately, however, we possess in iodoform, a material admirably adapted to our needs.

This drug is very sparingly soluble, so that it is not easily washed away from the wound, but enough is constantly dissolved to exert a decidedly antiseptic influence upon the fluids that come in contact with it.

A proper dressing of a wound through which urine is escaping would be somewhat as follows: First, drainage would be provided for by a rubber tube reaching to the deepest part of the wound. It is especially important to guard against any obstacle to the flow of the urine. In fact, when the bladder is opened it should be treated like an abscess cavity, and we should endeavor to prevent the urine being pent up in the former just as we should try to avoid retention of pus in the latter. Thorough drainage quickly relieves a fermented, foul condition of the urine.

The surface of the wound should then be lightly dusted over with powdered iodoform and some charpie filled with the same powder, or some iodoform gauze should then be lightly laid into the cavity. This should not be packed in, for fear of hindering the escape of the urine. This inside dressing may be left in place for from twenty-four to forty-eight hours. Outside of it there should be a large pad of some absorbent material (oakum, peat, or wool wool), which is to receive the urine, and can be often changed.

In addition to these local surgical precautions there are certain drugs which, when administered internally, render the urine mildly antiseptic, and it is easy to see of what advantage it may be to thus hinder fermentation.

First among such agents, we may mention benzoic acid and its salts, the benzoates of sodium and ammonium. By their administration, the urine is rendered acid. Benzoic acid, which has decided antiseptic properties, is eliminated as such by the kidneys, and has usually so marked an effect upon the contents of the bladder that fermentation then speedily ceases unless it is kept up by some considerable obstruction or other cause which cannot be relieved.

Eucalyptus has also considerable reputation as a corrective of fermenting urine.

Bartholow says "No remedy which the author has hitherto used has seemed to him so effective in *chronic catarrh of the bladder* as eucalyptus. The urine, during its administration, acquired a strong odor of eucalyptol, and to its local action on the mucous membrane is to be attributed the therapeutical effect."

### SOME FORMS OF DYSMENORRHEA AND THEIR TREATMENT.

BY F. H. DAVENPORT, M.D.

Assistant Surgeon to Free Hospital for Women.

In a society of this kind, subjects which lie on the border-line of general and special practice, will, other things being equal, be of most interest. I have, therefore, selected dysmenorrhea, a familiar, nay, almost a trite subject, hoping that it will excite discussion, and elicit facts of practical bearing on diagnosis and treatment. Its claims are two-fold: first, its frequency; second, its obscurity. Every practitioner meets with it, treats it successfully or otherwise, and very often the latter; every writer on diseases of women devotes pages to its consideration, and has a possibly, to him, satisfactory explanation of its several forms, the varying tenor of which are a proof of the difficulty and obscurity which surround the whole subject.

It is not my purpose to say much of the pathology of dysmenorrhea, but to illustrate clinically some of its forms, and the various methods of treatment which have seemed best suited to the given case. And here in the outset let me say that I conceive that quite as much of the advance in our knowledge of this subject, will be from more accurate clinical observation as from the labors of the pathologist in the post-mortem room. Structural changes, I am convinced, play a subordinate part in the production of pain at the time of menstruation, and I think the general trend of observation and experience on this point, goes to prove this where progress is being made. It is on the line of more thorough and minute study of the time of occurrence, seat, character, and duration of the pain; and I believe that as large numbers of facts bearing on these points are collected, valuable deductions can be drawn as to the cause, and as to the proper treatment to be pursued.

My intention in this paper is briefly to relate isolated cases of different types, to give the different methods of treatment pursued, and to make such comments as they seem to demand.

CASE I. Mrs. A., thirty years old, ten years married, has had two children, the last eighteen months before date of consultation. Labor was induced at eight months on account of convulsions. She remained in bed three weeks, but her convalescence was slow. Her menstruation began at fifteen, and was regular and unaccompanied by pain until its reappearance after her last confinement, since which time she has suffered to a marked degree. The flow is regular, lasts five days, but is scanty, requiring the use of but three or four napkins. She has no pain on the first or second day, but as the flow begins to diminish, she has severe pain in lower part of the abdomen, and through the back and hips, confining her to bed. She compares the pain which she suffers at these times to labor pains. Between the menstrual periods she complains of constant backache and pain in the hips, especially on the right side. There is no leucorrhœa. Examination de-

tected nothing abnormal except tenderness, and apparent increase in size of both ovaries. In order to be sure of the condition of the ovaries examination under ether was advised, which showed that both the organs were in position, but felt hard, the left was as large as an English walnut, the right somewhat smaller.

The application of a leech to the cervix uteri, one or two days before the expected sickness was advised, and was carried out for several months with complete relief, not only to the severe pain at the time of menstruation, but to the constant backache during the interval. Lately it has been thought necessary to apply the leech only every second month, except when from exceptional fatigue the patient fears she may have a return of the pain.

This case, for the notes of which I am indebted to Dr. W. H. Baker, under whose care the patient first came, seemed to be one of congestion of the ovaries, unrelieved by the scanty flow, and it was expected that the increased loss of blood by the leeching would so far lessen the engorgement as to relieve the pain, an expectation which was fully realized. The cases of which this is a type, are not infrequently met with. Sometimes the trouble seems to be with the ovaries as in this case, sometimes with the uterus. For relieving these forms of engorgement, wherever it may be, the application of a leech is superior to anything I know. The prolonged steady suction determines a flow of blood in the direction desired, which is analogous to a natural fluxion, and persists after the leech has been removed. The difficulties attending this procedure, and the time it occupies, have influenced its abandonment in favor of scarifying or puncturing the cervix. I have tried both methods and have satisfied myself, especially with regard to puncturing, that not only is the flow scanty, and relieves only the superficial blood-vessels, but the pain which accompanies and follows this process in a sensitive womb, is by no means to be lightly thought of.

There are two forms of dysmenorrhea in which I would apply leeches. First, when the pain comes on several days before the flow begins, usually starting in the region of one or both ovaries, soon followed by backache and a feeling of weight in the pelvis, and either wholly or partly relieved when the flow is once established. The flow is usually in such cases not very profuse. The impression made, is that the congestion comes too soon, and continues too long, and that nature vainly attempts to relieve it by the starting of the flow. Where it is scanty or delayed, a combination of circumstances which is very apt to occur together, the abstraction of a moderate amount of blood by the application of a leech to the cervix will often relieve the pain. In not a few of these cases we find enlarged and prolapsed ovaries, evidently the result of the long-continued congestion. In such cases the application of a leech before each menstrual flow, for several successive months, will in addition to relieving the pain, often markedly diminish the size and improve the position of these organs.

A second condition in which I would recommend this procedure is when the pain occurs principally after the flow is over. In these cases there is little trouble beforehand. Menstruation begins well, but the flow very quickly stops, and leaves a most annoying sense of weight and fullness in the pelvis, the back and head, a general feeling of heaviness and inertia, which is evidently due to unrelieved congestion. Here, too, a

few ounces of blood drawn in this way will be followed by relief. If the pain is wholly post-menstrual, the leech had better be applied then; if it comes on in the course of the menstruation it will probably be more efficient if applied before.

The operation itself was, I confess, until within the last two or three years, a severe trial to the patience. Nothing can be more aggravating than to attempt to induce a sluggish leech, to wander the length of a long glass tube, and seize hold of the proper spot. Of course if the patient was particularly sensitive, and your own time was limited, the leech would absolutely refuse to do anything. I was not quite ready to adopt the method advocated by Courty of turning into a cylindrical glass speculum placed against the cervix, a dozen leeches, slugging the end with cotton, and after waiting a certain length of time, turning out the gorged leeches and the clots. I attempted to devise an instrument that would take the place of the leech, but after one or two trials gave that up as impracticable.

It was by the suggestion I think of Dr. W. H. Baker that the following method was put in practice. It was found that by seizing the leech with the uterine forceps a short distance from the head, and holding it against the part to which it is desired to apply it, it usually takes almost immediate hold with a good deal of vigor. This can be watched, and the flattening out of the sucker-like head, which occurs when the leech is inserting its sharp jaws can be seen. The grip of the forceps is then slowly relaxed, and the leech usually goes on to satisfy himself. Very little fear need be entertained of damaging the leech by this manoeuvre. The pressure of the uterine forceps when closed and even locked, does not affect the suction-power of the leech subsequently, in the least. The point of election at which to grasp the animal is about half an inch from the head as it is elongated.

This method makes the application of a leech to the cervix a comparatively easy matter. With the patient on the side the cervix is brought into view with Sim's speculum, and the leech applied directly to any part of it with the forceps. Should it fail to take hold the first time, it may be quickly seized again and reapplied.

The amount of blood which the leech itself abstracts is but a small part of what should flow. The quantity which practically is usually sufficient to relieve congestion may be estimated at what will saturate three or four napkins, as women usually wear them. Ordinarily it will cease of itself when about that amount has been lost, sometimes earlier. If the patient is to go some distance, it is well to provide her with something to apply in case the flowing should be profuse, as occasionally happens. A cotton dressing with powdered alum to push up against the cervix will answer as well as anything.

CASE I. Mrs. B., twenty-nine years old, consulted me in March, 1881. She had been married for seven years, had always suffered from dysmenorrhœa, and had never been pregnant. The pain came on with the advent of the menstrual flow, was intermittent in character, most severe the first and second days when the flow was most abundant, and accompanied by the passage of small clots. Following the expulsion of these clots there was relief from the pain for a time. No leucorrhœa, and no marked pain at any other time. Examination showed ante flexion of the body of the uterus, with a stricture of the canal at the internal os. The small uterine probe entered, but the

sound could not be made to pass. Under ether I divided the os internum bilaterally with the nitroto, until the canal easily admitted Peaslee's sound, and then inserted a tent of styptic cotton which was allowed to remain for four days. She remained under observation about a year, during which time she was free from dysmenorrhœa, but had not become pregnant.

The operative treatment of dysmenorrhœa is, of course, only applicable when we have to deal with the obstructive form due to actual or spasmodic stricture, or to a narrowing of the calibre of the uterine canal by a flexion. I think more careful observation will show that the importance of the last two factors, flexion and spasmodic stricture, has been overrated. A recent writer in one of the English medical journals, gives the report of a number of women examined by him, who suffered from severe intermittent pains at the menstrual period, which previous examination had led him to suppose must be caused either by a spasmodic stricture or a flexion. His examination was made during the flow, and when the pains were at their height. He found that so far from there being any narrowing of the canal, it was more patent and straighter than at any previous time. His theory was, that the congestion of the uterus made the body firmer, and the canal straighter. It is true that these cases were few, and more evidence is needed; but I am convinced that spasmodic obstructive dysmenorrhœa has had too much importance assigned it. There remain for consideration the cases of true stricture which we not infrequently meet with where we have a rigid narrowing of the internal os, which only admits a small probe. These are the cases where operative measures are imperatively called for.

Until recently, in this country at least, Sim's operation by dividing the stricture with the knife, has been the favorite one for the relief of this trouble. Goodell, of Philadelphia, has lately published a paper in favor of the procedure of stretching the canal forcibly, which is now on trial by the profession; and if it makes good all that the author claims for it, bids fair to supersede Sim's operation entirely. Goodell has practised it for many years, having had the unfortunate experience of losing two patients after the operation by the knife, and his opinion as to the efficacy and safety of division is very decided. A few cases have been operated on by this method at the Free Hospital for Women, but it is too soon to speak of results. The reaction after the operation, however, is very slight. Its effect on sterility, which is usually associated with dysmenorrhœa in this class of cases, has been favorable. The instrument which Goodell recommends, and which we have found effective, is Ellenger's dilator. The advantages of the instrument are, that while it is strong enough to dilate the cervix, even when quite rigid, it is not so powerful that there would be danger of rupturing the uterus, and the graduated scale is a constant guide as to the amount of dilatation reached at any given time.

CASE II. Mrs. C. first came under my care at the out-patient department of the Free Hospital for Women, May, 1881. She had been married eight years, and had never borne children. Menstruation began at fourteen, and had always been accompanied by severe pain, especially the first day. The flow lasted three or four days, but was scanty, requiring the use of but four napkins. There was found a condition of anteversion and flexion, with narrowing of the canal. A Graffley-Hewitt cradle-pessary was introduced, which, however, failed to relieve the dysmenorrhœa. She was then

directed to come just before the flow was expected, and the sound was passed. This was followed by marked relief to the pain, and this treatment was repeated for several months. As she had a large uterus, three and a half inches in depth, and had a good deal of persistent pain in her back, Dr. J. W. Elliot, under whose care she came at this time, advised her to enter the Hospital for more thorough dilatation and exploration. She entered in November, 1881, and after previous dilatation with tents, the interior of the uterus was scraped with the curette, and a small amount of a fungoid growth removed. In February, 1885, she reported that the pain in the back disappeared entirely after the operation, that she had three painless menstrual periods, and then became pregnant.

This case is interesting because the dysmenorrhœa and sterility seemed to be dependent upon different conditions. The dysmenorrhœa was easily relieved by the passage of the sound just before the menstrual flow, pointing to some slight stricture of the type we have been accustomed to call spasmodic, as its cause. The sterility was only relieved by a more thorough dilatation, and the removal of a small amount of a fungoid growth.

The course of treatment employed for the painful menstruation in this case would naturally be suggested by the permanent good effect of forcibly stretching the cervix uteri, and especially the internal os, in cases of marked obstructive dysmenorrhœa. For the less severe forms, especially those cases where the examination shows a moderately patent canal, and where prolonged steady pressure will be followed by the passage of the sound, moderate dilatation just before the flow is expected, is often of service. Such result may be obtained, as in the case reported, by the passage of the sound or several gradually increasing numbers of Hank's dilators; or by passing in a small laminaria tent of less diameter than the uterine sound, and removing it in twenty-four hours, or earlier if the flow comes on. The carbolyzed douche should be taken two or three times while the tent remains, and the patient should be kept in bed. When the patient cannot be seen at the time the tent should be removed, it is a safe procedure to make a small tent of slippery-elm, and place that in the cervical canal. A string may be so fastened to this, that the patient can remove it herself at the proper time.

CASE IV. Mrs. H. applied at the Free Hospital for women in April, 1882. She was twenty-four years old, had been two years married, and had never borne children. She complained of severe headaches, pain in back, a frequent desire to urinate, and irregular and painful menstruation. Her menses occurred usually, about every five weeks, though sometimes the interval was longer. The flow lasted five or six days, and was accompanied by a good deal of pain, especially the day before and the first day. Examination showed retroversion and flexion of the uterus. An ordinary Hodge pessary was introduced, which gave some relief, but not as much as was desired. More careful examination showed that the left ovary was prolapsed. In the kneel-est position the uterus was replaced, and a Thomas bulb pessary adjusted. A week later, the patient reported herself as perfectly relieved of the headache, and ten days subsequently menstruated with less pain than for years.

This case illustrates that form of dysmenorrhœa dependent upon displacement of the uterus. It is in my experience, rare for marked dysmenorrhœa to occur as

a symptom of a backward displacement. Some increased pain and discomfort at the time of the menstrual flow may be one of the results, but is by no means the principal symptom with forward displacements; on the contrary, it is much more common; and in these cases we are very likely to find that peculiar ante-flexion of both body and neck, the latter having a conical shape, and associated very often with narrowing of the canal at some point, which we have learned to regard as almost pathognomonic of dysmenorrhœa and sterility.

The evident course of treatment to be pursued in these cases of pain at the time of menstruation associated with displacement, especially of the backward variety, is to replace the uterus. This will not usually hold out the prospect of so much relief in the case of ante-flexion as some of the operative procedures mentioned before; but with retro-flexion and version, the result will oftentimes be very satisfactory.

These various methods that I have spoken of, comprise the more obvious forms of operative and mechanical treatment for dysmenorrhœa. I have confined myself to them because the medicinal treatment of this trouble, which after all, is but a symptom, seems to me in the vast majority of cases, to be but palliative. Opium, cannabis indica, viburnum and alcohol, will often give temporary relief; and, where no structural cause can be found, the removal of which would promise permanent relief, it is our duty to relieve the pain by any means in our power.

#### THE QUESTION OF A VITAL PRINCIPLE. A REPLY TO PROFESSOR DWIGHT.

BY MORTON PRINCE, M.D.

*Physician for Nervous Diseases to Out-Patients, Boston City Hospital.*

DR. DWIGHT begins his paper (in the number of this JOURNAL for June 4th), by remarking: "To the student whose ideas of philosophy have been gained not only from so-called popular science, but from the teaching of many men eminent for their knowledge, a vital principle seems useless and absurd. In fact there is something comical in the surprise with which young men whose teaching has been solely materialistic learn that any one of any scientific attainment should presume to defend it."

As one whose ideas have been gained from "men eminent for their knowledge," I confess that to me a "vital principle seems useless, even absurd," and still more useless and absurd now that I have read Dr. Dwight's paper. I cannot, however, also confess to surprise on being told that occasionally a few scientific men — meaning thereby men who devote themselves to the examination and classification of concrete phenomena — should hold it. For in the first place, the fact that a man pursues physics, chemistry, anatomy, medicine, or any other branch of science, no more of itself qualifies him to hold an opinion on such subjects, than does the fact that he follows theology as a profession; and in the second place, observation shows that as soon as we overstep the borders of objective experience, there is no theory too absurd for people with otherwise well-balanced minds to adopt. For a man may be eminently scientific in his own department, but as soon as he transgresses the boundaries of that department his mind becomes most erratic in its action; as witness the number of scientists who believe in spiritualism.

To discuss Dr. Dwight's paper is a much more difficult task than it would seem to be at first sight. Not because of any significant fact or subtle logic that it may contain, but because such a task is very much like attempting to bring order out of a chaos of words. One feels very much as if one were brought into an old lumber room, wherein were piled in hopeless confusion all the old furniture and bric-a-brac of a hundred generations, and told to put things to rights; one hardly knows where to begin and what to clear away first. Whatever force Dr. Dwight's arguments may have, must be derived from their antiquity rather than their bearing upon the subject of a vital principle.

"I propose to show," he says, "that it is reasonable and even inevitable to admit a vital principle, and this by three distinct arguments, each based on observation." As Dr. Dwight carefully avoids defining with anything like precision of thought or terms what he means by a "vital principle," the task of disproving it is rendered still more difficult. To consider all the points involved in the paper in question would require far more space than is at my disposal, and would be out of proportion to the importance of the object. I shall therefore limit myself to the consideration, in the briefest possible space, of the most essential principles involved. Indeed, I should not enter into this discussion at all, were it not that Dr. Dwight's position as professor of anatomy might appear to some people to lend more weight to his opinions than they inherently deserve.

Dr. Dwight's first argument is based upon the phenomena of growth in plants and animals.

After mentioning the fact that organisms differ from non-living matter in that they possess the functions of growth and reproduction, and "that the living organism is one in a very different sense from that in which a heap of sand is one, or a wave is one," he asks "what makes the animal one?" The answer given is, "*It is clearly that principle which so regulates its nutrition that each part grows at its proper rate, aids the others, dwindles when its work is over, and, in short, forms a harmonious whole. Now there is also lately nothing that we know of in matter that can bring this about.*" (Italics not in original.)

What value the assertion that what makes the animal one is "clearly that principle which so regulates its nutrition," etc., can have beyond the fact of its being a mere assertion is difficult to comprehend. It clearly begs the question, as it assumes that there is such a principle in the first place, which is the question in dispute, and then utilizes it as an explanation. To say that "there is absolutely nothing that we know of in matter that can bring this about" again plainly begs the question; for he who does not believe in a vital principle, simply points to a plant and says: "there is matter pure and simple, and see there is something in matter which grows and reproduces, etc."

It can only be said that there is nothing in matter which can account for the phenomena of life, as exhibited in plants and animals, only on the assumption that all the "properties" of matter are exhibited by such combinations of natural elements as are found in inorganic or non-living substances. It is one of the canons of science, that we must not multiply causes before showing the inadequacy of existing ones. Before, then, introducing a "vital principle" to account

for vital phenomena, we must show the impossibility of material forces producing these results. This has never been done, but, on the contrary, the more intimate becomes our knowledge of the nature of matter, the more it becomes intelligible, if not *how*, at least *that* the "forces" of matter are capable of manifesting themselves in these phenomena. But for this to be intelligible it is necessary to have something more than the crude notions of matter that are popularly current. The fact that certain phenomena are observed associated with matter is *prima facie* evidence that these phenomena are due to the "forces" inherent in matter, and it is most unscientific to introduce an extra foreign principle as a factor until, at least, our knowledge of matter be extended to the farthest boundaries of human knowledge, and it be shown that it is impossible for such phenomena to be produced by material forces. The fact that phenomena of growth, reproduction, repair, etc., are associated with matter is, I repeat, *prima facie* evidence that these phenomena are caused by so-called material forces, and this is the only conclusion that can scientifically be maintained until it be shown to be impossible. The only standpoint from which I can conceive of the assertion being made, that "there is absolutely nothing that we know of in matter" which can cause vital phenomena, is that all one knows is limited to the crude and popular notion that matter exists as we perceive it. And I must believe that it is from this standpoint that Dr. Dwight writes.

It is a fact that our knowledge of a crystal of sulphate of copper, for example, consists of certain groups of sensations, such as color, hardness, acidity, etc., which are not in the so-called crystal outside of us, but are forms of our consciousness. These sensations are caused in us by something outside of us, some "force" or activity, which is unknown to us. This unknown force is called the Reality of the crystal. So that matter may be resolved on the one hand into a great number of bundles of sensations, and on the other hand into a great world of unknown forces. The former exists in us, the latter outside of us. The former are the modes in which we become conscious of these unknown forces but are not these forces themselves, which must not only be forever unknown to us, but they cannot even be translated into thought. It is these forces which are the real matter. There is every reason to believe that the different properties of different chemical substances are dependent upon the different combination of forces, which are the Realities of the chemical elements. "Further" (if I may be pardoned for quoting from what I have written elsewhere) "as the different combinations of the forces or Realities lying behind the atoms of inorganic substances exhibit themselves in the varying properties of such substances, so the various and more complicated combinations of the same forces in living protoplasm exhibit themselves in its properties or vital functions. By a still further combination of these activities (underlying the properties of the simplest form of living substance, a lump of protoplasm, and manifesting themselves in its vital functions), the primitive germs of consciousness arise, and we obtain for the first time a glimpse of what these forces of the unknown universe may be."<sup>1</sup> This is not the place to enter into any extended argument in favor of these views, nor have I any desire or intention here to prove the correctness

<sup>1</sup> The Nature of Mind and Human Automatism, 1885.

of this explanation. My purpose is merely to point out that this is a very possible, if not probable, interpretation of material (vital) phenomena, and instead of there being "absolutely nothing" there is a great deal in matter, when properly understood, capable of bringing about the phenomena of growth, etc. Until this or some similar explanation is shown to be impossible, the introduction of an extra-material element is most unscientific.

"The second argument" of Dr. Dwight is based on "the theory of sensation." But as this argument involves the whole question of the relation of the mind to the brain, it is one that is far too large in scope to be discussed in either the paragraph devoted to it by Dr. Dwight or the limits of a single paper. Suffice it to say that Dr. Dwight's statement of modern views is not in accord with those views as expressed by the best authorities.

"The third argument consists in the freedom of the will"; an argument, I may add, which has long since been consigned to the lumber room of metaphysical sophistry. Dr. Dwight concludes his argument by a quotation from Dr. Hammond, concerning the distinction of the mind and the soul. This quotation is introduced, the writer takes pains to assure us, "because it is a typical specimen of much that unfortunately passes for science." Dr. Hammond, after emphasizing the fact that by mind he does not mean soul, says: "With it (the soul), however, I conceive we have nothing to do, as far as science goes. Its very existence is a matter of faith, in which probably most of us believe, but which is altogether beyond the limits of proof, or even of investigation. There is nothing tangible about it. We should not know how to proceed to ascertain the existence of the soul."

I cannot express the same regret that this passes for science, for it is science of the most refined kind: it is the real coin, with the true stamp upon its face. I cannot help thinking that Dr. Dwight has been most unfortunate in his selection of passages for quotation; for every one, at all versed in scientific thought, will recognize at once that this passage shows that Dr. Hammond is possessed of a mind particularly well adapted for philosophical speculations, and thoroughly understands the limits of human inquiry. Dr. Hammond adds, "If the mind and the soul are identical, all these predisposing causes, if inherent in the parents, and which are capable of causing imbecility and idiocy in the offspring, are also capable of damaging the immortal soul that we believe God has given to every human being," etc. To which Dr. Dwight exclaims: "And this is what is palmed off on us as science!" The best advice I can give Dr. Dwight is to try Joseph Cook.

—A serious mistake was lately found to have been committed by a wholesale house in Philadelphia, which had been selling tartar emetic in place of Rochelle Salt, probably owing to the carelessness or ignorance of one of its workmen. A number of persons who had purchased Rochelle Salt at a retail pharmacy were taken violently ill, and the above fact was ascertained as being the cause of the illness. Presumably, the wholesale house succeeded in getting back all the tartar emetic thus sold, as no further cases of poisoning have since been reported.

## Reports of Societies.

### THE AMERICAN DERMATOLOGICAL ASSOCIATION.<sup>1</sup>

#### MYCOLOGICAL STUDIES IN *TINEA FAVOSA* AND *TINEA TRICHOPHYTINA*.

By Dr. A. R. ROBINSON, of New York.

The speaker prefaced his paper with a few general remarks. The epidermis of different individuals differs in susceptibility to these parasites. Children are more apt to suffer with *tinea trichophytina* and favus, while adults more frequently present *tinea versicolor*. All children are not equally susceptible. In many cases of parasitic disease there is impaired vitality previous to the development of the affection.

The speaker then gave an account of his investigations to determine the exact anatomical seat of the parasitic diseases in question and to determine the changes which they produced in surrounding tissues. The conclusion was that in favus, the rete is not affected until the latter stages when ulceration had made its appearance. The parasite confines itself more particularly to the corneous layer. The parasite of *tinea trichophytina* in some cases passes down into the rete, while in others it does not.

A number of sections were shown under the microscope which illustrated the points brought out in the paper.

#### DISCUSSION.

Dr. WHITE. — I would ask the reader what evidence he has that in ringworm and favus a decreased vitality is necessary?

Dr. ROBINSON. — I think that is found in the fact that it is exceedingly difficult to cure these affections occurring in broken-down subjects, until the general health is improved.

Dr. WHITE. — Is there any evidence that the fungus attaches itself more readily, or runs a more rapid course in unhealthy children?

Dr. ROBINSON. — Practical experience shows that. It is well known that in hospitals the disease will spread more rapidly than in private families.

Dr. WHITE. — I cannot agree with the speaker in the importance of depressed general health as a factor in the production of these diseases. I have never seen any necessity for internal treatment in these cases. Where the disease affects a superficial portion of the body it is readily removed, but where it involves a portion covered with hair it is difficult to cure. Although I think the improvement of the general condition has nothing to do with the cure of the parasitic trouble, yet it is of service in the restoration of the parts to their natural condition after the parasite has been destroyed.

Dr. PIERCE. — I must agree with Dr. Robinson that there is a relation between the condition of the general system and the rapidity of development and the rapidity of cure.

Dr. DURING. — I have always held the view that a particular condition of the epidermis was necessary for the growth of the fungus. The majority of cases of obstinate ringworm that I have seen, have been in individuals in poor health, but there are exceptions to this rule. What this peculiar condition of the skin is has not been determined.

<sup>1</sup>Continued from page 245.

DR. HEITZMAN.—As regards the constitution of the patient, I must agree with Dr. White. I have seen strong healthy persons covered from head to foot with tinea.

DR. DENSLOW.—I have recently seen a large number of cases of ringworm of the head and beard, but all the patients were well developed muscular subjects. These were cured without internal treatment.

#### ON THE STRUCTURE OF THE DERMA AND THE DEVELOPMENT OF ELASTIC TISSUE IN IT.

By DR. C. HEITZMAN, of New York.

The essayist drew attention to the fact that Professor Stricker, of Vienna, the acknowledged best microscopist of Europe, has now accepted his views concerning the life of basis-substance. Dr. Gartner (who was present at the meeting), Stricker's assistant, has brought from Europe an electric picture microscope, by means of which these newly-discovered facts can easily be demonstrated to a large audience, upon a screen. There are three varieties of basis substance, differing from each other in their chemical constituents, namely, the glue-yielding, basis substance proper, producing the spindles within the bundles of so-called fibrous connective tissue; the cement substance between the spindles; and the elastic substance developing along the edge of the bundles in advancing age and in some tumors. All three varieties are traversed by a delicate reticulum of living matter in connection with the protoplasmic cords, that fill the interstices between the bundles in the shape of a comparatively coarse reticulum. Thus it becomes intelligible that in morbid processes, not only the protoplasm, but also the basis-substance participates in an active manner. After the liquefaction of the solid fields of glue yielding basis substance, the bundles directly are transformed into inflammatory corpuscles from which starts every physiological and pathological new formation.

DR. W. A. HARDAWAY, of St. Louis, described

#### A CASE OF MULTIPLE MYOMATA OF THE SKIN ACCOMPANIED WITH SEVERE PAIN.

A. B., aged thirty-six years, married, with healthy children and good family history. Never had syphilis. Present trouble began a year ago. Changes in weather produced pains in the parts which have since become affected. To relieve these, firm pressure was made with the hand. Between the paroxysms, pain was not produced by pressure. Later the lesions presented themselves.

#### PRESENT CONDITION.

A strong hearty man, a peddler by occupation. The pains still persist, recurring at intervals of one night to a week. Each attack lasts two or three minutes and does not return the same night.

The growth is situated on the right side of the back in the mid-dorsal region, and the course of the growth is obliquely outwards. There are one or two of the elevations on the left side, three of the growths are as large as peas, others are small. The epidermis is not abnormal. On passing the hand over these growths, there is no hyperæsthesia, but on deep pressure in the neighborhood of the larger masses, the patient sinks morning to the floor.

One of the larger growths was removed and micro-

scopical examination showed it to be composed of smooth muscular fibre.

From a clinical stand-point, the case bears a close relation to the cases of neuroma which have been reported. The speaker concluded that certain new growths in the skin, accompanied with severe pain may be widely different histological structures. We are not justified in assuming that a painful tumor of the skin is a neuroma or fibro-neuroma simply from its clinical history, without a microscopical examination.

DR. DENNING.—It would be difficult to differentiate from the local appearances, the case described by Dr. Hardaway and that which I reported some years ago. It is not possible from a clinical stand-point, as has been said, to differentiate these growths, and we have to rely on the microscope. There is one point, and that is, in the case just described, no pain was produced by superficial manipulation, while in my case the pain was intense on the slightest touch, while firm pressure decreased the pain.

#### AN UNUSUAL CASE OF TYLOSIS ON THE HANDS.

By DR. R. B. MORISON, Baltimore.

The patient was a negro, aged 32, muscular, well developed and apparently healthy. By occupation, he was a fireman of a steamer and had occupied this position for ten years, shovelling coal, with the right hand grasping the upper portion of the shovel, and the left hand sliding up and down the handle. Two fingers of the left hand are worn off to the second joint, while the other two are going in the same way, the nails having nearly disappeared. On several occasions he has drawn pieces of bone from the fingers. There has been no pain at all connected with the affection. On this hand there are some large blisters underneath which there are red granulating surfaces, which are painless. There is no history nor evidence of syphilis. Specific treatment has been used without effect. The man obstinately refuses to give up his work, so that little could be done in the way of treatment.

DR. WHITE.—From the unusual change it would seem that there must have been some precedent change causing atrophy.

DR. TILDEN.—There is a good deal of resemblance between this case and the cases of perforating ulcer of the foot, and this would lead us to suspect a nervous element.

DR. WIGGLESWORTH.—This resembles in some respects anæsthetic leprosy, but it differs in other points.

DR. MORISON.—I am led to consider it a strictly local affection, from the fact that the hand which was most exposed to rubbing and to the heat of the furnace, was the one most affected.

DR. DENNING.—I should be inclined to consider the callosities a secondary condition. The occupation probably had something to do with the aggravation of the disease, but if the occupation had been different, there would probably have been a similar change. I should regard it as dependent on some deep change in connection with the nerves similar to that which occurs in perforating ulcer of the foot.

DR. MORISON.—That it was an affection of the nerve in the first place I can hardly admit. It may be that the continued congestion of the skin, dependent on his occupation, produced changes in the nerves or other part, which culminated in this affection. In referring to the literature of the subject, I find similar cases attributed to mechanical irritation.

## EVENING SESSION.

## THE RELATION OF HERPES GESTATIONIS AND CERTAIN OTHER FORMS OF DISEASE TO DERMATITIS HERPETIFORMIS.

By DR. L. A. DUHRING, of Philadelphia.

Attention was briefly directed to the previous articles of the reader on dermatitis herpetiformis, and to a paper showing its identity with the impetigo herpetiformis of Hebra; also to a preliminary note on the relation of this disease to herpes gestationis and other similar forms of cutaneous disease, read before the Association at the last meeting.

The object of the present communication was to prove the identity of so-called herpes gestationis with vesicular variety of dermatitis herpetiformis, and to show that the term herpes gestationis was a misnomer, the affection being found in men as well as women. Secondly, that certain other so-called forms of herpes, such as "herpes phlegmoideus," "herpes vegetans," "herpes pyramicus," etc., as well as certain cases regarded by the reporters as "peculiar forms of pemphigus," must be viewed as examples of this disease; and finally, that instances of the same affection were also met with in literature, under the title of hydroa, and under divers other captions. Numerous cases from English, French, and German literature were cited. The paper of Dr. Duhring was stated to be looked upon as supplementary to the preliminary note referred to, and embodied the results of considerable research into literature. If the views put forth proved to be correct, a great deal had been gained for dermatology in bringing these peculiar forms of disease together.

## DISCUSSION.

DR. WHITE.—I think that the term dermatitis herpetiformis is a misnomer. The disease should be called dermatitis multifomis. The herpetic element is often wanting.

DR. ROBINSON.—I agree with Dr. White, that the term dermatitis herpetiformis is too restricted, but I should prefer some term which does not indicate the pathology, until the disease is better understood.

DR. HYDE.—There are reasons why I should disagree with the last speakers. The term herpetiformis is preferable, if for no other reason, because it is suggestive.

DR. FOX.—I wish to show here a photograph of a case which might be mistaken for dermatitis herpetiformis, namely, erythema multifomis. This disease should be placed in strong contrast with dermatitis herpetiformis.

DR. DUHRING.—The name dermatitis herpetiformis was adopted because it seemed the least objectionable. The herpetiform character of the disease is to my mind characteristic. The term dermatitis multifomis is already employed to designate a form of skin trouble, and dermatitis herpetiformis expresses an important variety of that affection.

## MYCOSIS FONGOIDES.

By DR. G. H. TILDEN, of Boston, Mass.

The speaker described the case of a man, aged 28 years before he came under observation. Three years before, several red, desquamating spots had been observed on the elbows. Several months later, erythematous spots accompanied with pruritus were noted. These lesions retained a dry, scaly character. There

were no vesicles or pustules. At the end of a year several red nodules appeared on the face and throat. These, however, disappeared. Later, a small papule appeared on the right thigh and increased in size. From this there exuded a thin fluid. This was followed by the development in many parts of the body, particularly, the axillæ, groins and neck, of similar lesions, in some cases reaching the size of a hen's egg. After a time, there was superficial erosion of some of the tumors, but these excoriated tumors remained firm in consistence. But some of the masses which were covered with epidermis were soft, but there was no evidence of the formation of pus. There was also indolent enlargement of the lymphatic glands. The general health continued good. The patient passed from observation and died at the end of three years and a half.

The report of the microscopist who examined the tumors was read. His opinion was that the growths consisted of the formation of lymph tissue in corium.

Reference was then made to the literature of the subject and the various cases, some 30 in number, which had been reported were given, and the symptoms and course of the disease described. Sections of the growth were also presented for examination.

DR. WHITE.—This patient was under my care during the last stages of the disease, and he presented the changes which have been described. Some of the larger growths disappeared. During the last months of his life the man was taking arsenic. Death resulted from the occurrence of diarrhea.

DR. ROBE.—Four years ago, I saw a case of what I think to have been the same affection. The man, 62 years of age, had a multitude of these tumors. Several had been extirpated before he came under my care, but there was recurrence with this fungoid appearance. The man was given arsenic, but he died from exhaustion. No autopsy could be obtained. As far as could be detected, there was no affection of the liver or spleen.

DR. MORISON.—I have seen a similar case, which was diagnosed multiple sarcoma of the skin. I take the microscope to settle the question in these cases.

DR. FOX.—We have seen one or two similar cases in New York. Should one come under my care, I should try the effect of calanoga oil. Judging from its effects in other cases, it should be useful.

DR. HARDAWAY.—In a case of alveolar sarcoma, which I reported, the disease has existed fifteen years, but the clinical features are about the same as they were years ago. There is marked enlargement of the lymphatic glands. The general condition is good.

DR. HERTZMAN.—The description of the microscopic appearance is that of a lympho-sarcoma, and the examination of the specimen confirms me in the view that this was a case of lympho-sarcoma.

DR. SHERWELL.—To show the amount of involution that may take place, I would refer to a case of melano-sarcoma under my care. The man was treated with arsenic, mercurials, and so forth. After six months' treatment, the tumors have almost entirely disappeared. There was not the slightest evidence of syphilis.

DR. FOX.—In regard to the use of calanoga oil, I have seen it used in a case of leprosy. There is now not a trace of leprosy, except the contraction of the fingers, which is, however, a secondary condition. It has failed in many cases, but there is sufficient to justify a trial of it in the chronic inflammatory affections referred to to-night.

# URETHRAL IRRITATION IN THE MALE AS A CAUSE OF CERTAIN NEUROSIS AND OF ACNE.

By DR. L. N. DENSLOW, of St. Paul, Minn.

He prefaced his remarks by a brief review of the cases of contracted meatus, reported by Dr. Otis. He then gave an account of a number of cases coming under his observation, in which there were reflex conditions associated with conditions of the urethra, such as contracted meatus, stricture, and excessive sensitiveness of the prostatic urethra. In these cases, removal of the urethral trouble produced an alleviation or cure of the affection to which attention has been directed. He also reported four cases of severe acne, in which the same treatment had been followed by marked improvement, or cure of the skin disease. In some of the cases, ergotin was also employed. The speaker said that he simply reports the cases as so many observed facts, and did not express any theory. He would keep the cases under observation and at a subsequent meeting give a further report.

DR. WHITE.—In regard to the use of ergot, I have employed it in obstinate cases, without seeing the least benefit from its use.

DR. TAYLOR.—I would object to this promiscuous cutting of urethras, which is so common at present.

DR. SHERWELL.—I believe that acne is largely a reflex disorder, but I am not in the habit of introducing a sound in every case of acne. I get good results from other measures. I think that it is valuable in severe cases. I strongly believe in the action of ergot in connection with local applications, especially in females.

DR. HYDE.—Many of the cases with urethral trouble associated with acne, are patients who probably have been taking for some time balsamic preparations, and as a result they have the development of acne. I would suggest to Dr. Denslow, that he take this point into consideration.

DR. DENSLOW.—In all the cases reported, the acne had existed since puberty. The patients were not hypochondriacs and they were not masturbators. I am satisfied that no drugs had been used in any of them.

Adjourned.

## FRIDAY, THIRD DAY — MORNING SESSION.

### REMARKS ON ELECTROLYSIS AND OTHER PRACTICAL TOPICS.

By DR. C. HEITZMAN, of New York.

The reader spoke very highly of electrolytic epilation. For this purpose he uses the Leclanché battery. Six cells of this battery have the advantage of steadiness, lack of pain, and lack of reaction, when applied to the face of the patient. He employs a needle devised by Leiter, of Vienna, which permits the depth to which the needle penetrates to be measured.

He has had good results from electrolytic destruction of dilated blood vessels in the face, less satisfactory results in the treatment of port-wine marks, where a permanent cure is only exceptionally attainable. Sodium ethyl is highly recommended by some for the destruction of angioma of the face, but it is in no way superior to nitric acid.

The speaker maintained after observing two hundred cases of falling of the hair, caused by seborrhea, that the method he recommended in 1876, gave fair results. This is the application of a ten or twenty per cent ointment of crude oleum rusci in vaseline and paraffine.

For the removal of freckles, the speaker used an oint-

ment recommended to him by Wertheim, of Vienna. The preparation is as follows:

R Hydragr. Ammon. Muriat . . . . .	gr. 3.75.
Magist. Bismuthi . . . . .	3.5.
Ungt. Glycerina . . . . .	30.0, M.

This is to be applied in a thin layer, every night, and in four or six weeks the result is highly satisfactory.

As to the permanency of the cure, the speaker was unable to state.

In regard to the re-appearance of hair after removal by electrolysis, it was considered to be due to the growth of the fine hairs which was increased by the transference to them of the nutrition which should have gone to the hairs removed.

DR. HYDE.—Dr. Heitzman has touched upon the important point in the removal of hair by electrolysis. The question is not what will be the result at present, but what it will be in the future. The electrolysis produces a hyperemia which tends to stimulate the growth of the remaining hair. I have found the rectified oleum rusci very valuable. I would ask what is the test for the crude oil.

DR. FOX.—In regard to the treatment of angioma, I have used nitric acid, making the application in the form of small dots one fourth to half an inch apart, with great advantage. In one case in which a nevus occupied half the body, I used this treatment with much success.

In regard to the return of the hair after electrolysis: If the needle is carefully inserted and gentle traction is made on the hair, that hair will not return. In some cases there is a constant increase in the downy hairs from some cause, but they are exceptional cases. I do not think that the removal of hairs increases the growth of others. In one case, that of a young woman with a strong beard, I removed by actual count, eight thousand hairs. This process required two or three years. Since then it has been necessary to remove only a few dozen hairs.

DR. ROBINSON.—I have used a similar ointment for the removal of freckles, but its effect is only temporary. I think that the growth of the remaining hairs is increased by the removal of a portion.

DR. WIGGLESWORTH.—For the past fifteen years I have used the following ointment, which is almost identical with that mentioned by Dr. Heitzman.

R Hydragr. Ammon. . . . .	parts 10.
Bismuthi Subnitrat . . . . .	" 10.
Vaschine . . . . .	" 100, M.

DR. DEHRING.—I consider the oleum rusci valuable in seborrhea of the scalp. The objection to it is its disagreeable odor. I have also used in chronic seborrhea of the scalp, a preparation of sulphur, but I do not consider it as efficacious as tar.

DR. HARDWAY.—I have performed the operation of electrolysis for ten or twelve years, probably longer than any other member of the Association. I use the irido-platinum needle which has the advantage of being bent and it is not likely to pass through the follicle wall. The moment the follicle is entered, there is an escape of sebum. One case, that of a woman with a heavy black beard, has been entirely relieved. Electrolysis with a fine needle affords a method of getting rid of freckles. The plan is to dot the needle over the surface covered by the freckle.

DR. HEITZMAN.—The percentage of recurring hairs is greater in some situations than in others. In the submaxillary region, it is greatest. The oleum rusci crudum

is better than the rectified oil. To test it, add alcohol to a small portion of the oil and paint it on the skin. If it dries quickly, leaving a black bark, it is the crude oil.

#### ON SYPHILITIC RE-INFECTION.

By DR. R. W. TAYLOR, of New York.

The speaker first referred to the literature of the subject and gave a brief review of the authentic cases on record, giving the names of the reporters. The number of cases previously reported is between thirty and forty. To these the speaker added the histories of three more. A fourth case has been observed by him, but as the complete history was not prepared, it was not given.

CASE I. A bar-keeper, aged 25 years. Was first seen in 1868 suffering with gonorrhea. Three years previously had had indolent enlargement of the lymphatic glands in the groins. Examination showed the presence of lymphatic enlargement in certain regions. Inquiry into the history showed the existence of a chancre three years before, which had been slow in healing. About two months later, he became sick and suffered with a roseolous eruption, sore throat, falling of the hair and rheumatic pains, worse at night. Under treatment he improved, but afterwards exhibited a papular eruption. He was then seen by Dr. Van Buren, who pronounced the case one of syphilis and ordered mercurial treatment. He recovered after two years, but of his own accord continued the treatment two years longer. He then remained well until the attack of gonorrhea.

In February, 1870, he again appeared, presenting a typical indurated chancre on the cutaneous aspect of the pubes. It presented every evidence of a primary infection. Later, a papular syphilide appeared over the body. There were several mucous patches on the pillars of the fauces, and the throat was red and swollen. The joints soon became the seat of nocturnal pains. The patient also presented a form of syphilitic epilitis. Under mercurial treatment, there was some improvement, but a year later there were some tertiary manifestations. By 1874, he seemed very well. During the next three years, there was no evidence of syphilis, but he continued the mixed treatment.

He was again seen in the fall of 1882, when it was learned that his good health had continued and that he was the father of a healthy child. The child was examined and no evidence of hereditary syphilis detected.

CASE II. Had in June, 1873, a typical indurated chancre, followed by distinct secondary symptoms, which disappeared under treatment. He then passed from observation. In February, 1874, he presented several necro-tubercular lesions on the outer aspect of the forearm. He then remained under treatment six months. In January, 1875, he had spots of thickening of the periosteum of both tibiae; he was again treated, with benefit. In June, 1876, there was a typical indurated nodule on the prepuce, from which extended indurated lymphatics passing to the inguinal lymphatic glands. The incubation of this sore had been about twenty days. This was followed by nuchae, sore throat, swelling of the post cervical and epitrochlear glands. Over the body and arms there was a fine mottling of light pink color. The patient then went to Europe, and was not seen until March, 1885, when it was learned that the symptoms had been well marked, and that he had been under treatment for them with several Continental physicians.

CASE III. Age 41. Had had a typical indurated chancre in 1874. There had been inguinal adenitis, followed by roseola, falling of the hair, and later by severe iritis of the right side. He was treated with mercury.

In February, 1882, he returned with a typical hard chancre. In April, he became sick, had rheumatic pains and a mixed eruption of erythematous and papular syphilide. In May, inflammation of the iris of the right eye again appeared. In 1883, he had a late secondary rash.

These cases were reported with the object of throwing some light upon the natural history of second infections of syphilis. In all these cases, relapsing indurations were carefully excluded.

DR. HYDE.—In my experience, I have had but two cases of re-infection of syphilis, where I was perfectly sure of the fact.

#### OBSERVATIONS ON THE OLEATES.

By DR. H. W. STELWAGON, of Philadelphia.

In regard to the chemistry and preparation of the various oleates, both as to their manufacture by the direct combination of the acid with the base, and by double decomposition, almost, if not entirely as much can be found in the English translation of Gmelin's "Handbook of Chemistry," published 1866, as in the writings of the past several years.

Of all the oleates, those of mercury, zinc, bismuth and lead, have a place in the treatment of diseases of the skin, and in view of their costliness, the seeming unavoidable frequency of badly-made preparations, the disagreeable oleic acid odor, and the irritation so frequently observed following their use, it is probable that of these four, the mercuric oleate is the only one that promises to retain a permanent value. This last is especially valuable in ringworm of the scalp; but for immersions in the treatment of syphilis, it is of doubtful utility, as it is questionable whether it is absorbed. Oleate of copper, which has been so highly recommended for ringworm of the scalp, is not comparable in that affection to oleate of mercury, or to tar and sulphur preparations.

#### DISCUSSION.

DR. TILDEN.—I agree with Dr. Stelwagon that oleates are not as useful as ointments.

DR. WIGGLESWORTH.—I have practically renounced all oleates except the oleates of zinc, lead and mercury, as a parasite.

DR. DEHRING.—My experience with these preparations is in accord with that of the reader of the paper. I have employed the oleate of copper in varying strengths in thirty or forty cases of ringworm, but it seemed to exert no influence whatever. These were, however, obstinate cases. Other methods of treatment were afterwards tried, and they were finally cured. As to its efficiency in acute forms of ringworm, I am not prepared to speak.

DR. HEITZMAN.—I have tried the oleate of copper in chronic cases of ringworm, without any result; but in the acute cases, it cures after a time. It is not as efficient, however, as the preparation recommended by Dr. Taylor; that is, four grains of bichloride of mercury to the ounce of tincture of myrrh.

DR. FOX.—I should like to refer to the comparison between oleates and vaseline. It has been claimed that the oleic acid and animal oils are better absorbed than

these other preparations. As a matter of experience, I have found that vaseline makes a better base for the majority of ointments than do the animal oils. I have also found vaseline a most soothing application to the skin.

Dr. TAYLOR.—I agree with the author of the paper, I only use the oleates of mercury and zinc; but I never rely on the oleate of mercury when the ointment can be obtained.

Dr. HARDWAY.—I have almost entirely discarded the oleates. In some recent cases, the oleate of copper has seemed to be successful, but in chronic cases it entirely failed.

#### A CASE OF SYPHILITIC APHASIA AND PARAPLEGIA FOLLOWED BY DEATH, WITH AN ACCOUNT OF THE AUTOPSY.

By Dr. L. N. DENSLOW, of St. Paul, Minn.

The object of the author was simply to put on record a case in which an autopsy was obtained in early syphilitic cephalalgia. The patient was seen in consultation April 29, 1885. Two months previously, the patient had begun to suffer with severe headache, worse at night. There was also a papular eruption. He acknowledges the existence of a sore six months previously. Iodide of potassium with chloral had been given, two weeks later, the patient was free from pain, but it returned one month afterwards, when the patient stopped taking medicine. Iodide of potassium was again given with the effect of relieving the pain. Aphasia and paraplegia then developed, and the patient died four days later, and within nine months of the initial lesion.

At the autopsy, the dura mater, along the superior longitudinal sinus, was thickened and adherent. There were numerous small gummata in the pia mater, situated along the right border of the longitudinal sinus, and extended back to the fissure of Sylvius. The pia mater exhibited the evidences of simple acute inflammation.

Adjourned.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES H. WILLIAMS, M.D., SECRETARY.

APRIL 5th, 1885. Dr. CABOT read a paper on

#### "THE APPLICATION OF ANTISEPTIC PRINCIPLE TO GENITO-URINARY SURGERY."

which will be found on page 215 of this number of the JOURNAL.

Dr. F. H. DAVENPORT said that some years ago, when the catheter was freely used after operations, cystitis often occurred; even now it is often necessary to use it for twenty-four or more hours after operating, but by insisting on the nurses following definite instructions, the number of cases of cystitis has been much lessened.

The nurses are directed to see the meatus urinarius before attempting to pass the catheter; in case of failure to pass it they are to carefully wash off any vaginal discharge from the instrument before making a second attempt; and when not in use the catheters are to be kept in an antiseptic solution.

Dr. FITZ proposed passing metal catheters through the flame of a lamp before using, to sterilize them, as with needles used for pure cultures.

Dr. F. B. HARRINGTON had found a glass funnel,

to the lower part of which a rubber tube was attached, the best and simplest instrument for washing out the bladder.

The Secretary called attention to a feature of Dr. F. H. Williams' three-way cock for irrigating the bladder or other purposes, namely, the suction of the exit tube, which was sufficient to carry small clots of mucus, etc., through the eye of the catheter without necessitating the removal, and that the amount of suction was very easily regulated by the length of the exit tube.

Dr. CABOT said that there was often more pain when the bladder was emptied artificially and the walls drawn together, than when the fluid was simply injected and the bladder left to empty itself through the catheter.

Dr. TILDEN insisted on the care needed to ensure cleanliness of the instruments; he had been in the habit of using a toothbrush with boiling water and a soap containing one-half of one per cent of corrosive sublimate to clean instruments after operations. He uses as an injection after urethrotomy, a solution of 1 to 10,000 of corrosive sublimate, and has not had a case of chill or rise of temperature following the operation since the use of these injections. He advised against leaving a catheter fastened in the urethra, as it serves as a source of irritation and gives a road to germs which may set up a septic inflammation.

He mentioned a case of perineal section, where, four days after the operation, an old bougie was used to pass into bladder; two days later the patient had a chill and the urine showed masses of micrococci, which were probably first introduced with the instrument. At the Boston Dispensary he had tried injections of corrosive sublimate in cases of gonorrhoea, but in only a few cases had any good resulted. He considered this due to the infectious material soon passing through the walls of the urethra into the tissue beyond, where it could not be reached by a germicide injection, and that these would be of service only in the early stages of the trouble. For his own use he preferred a syringe for injecting, but when placed in the patient's hands, some form of hydrostatic pressure, like the glass funnel with rubber tube, was better.

Dr. CABOT thought that in some cases it was necessary to have the catheter remain in the urethra, though it was not done as much as formerly. In cases where the operation was done on a posterior stricture, but not an anterior one, there is greater danger than if a free drainage of urine had been established by dividing both; in cases of bad stricture, where division had been done, it was a mistake to let the cicatricial tissue lie in old position of apposition and not keep it apart with a catheter. He thought the danger of introduction of germs between the catheter and the urethral wall could be avoided by tying a pad of antiseptic cotton closely to the catheter so that it would cover also the end of the penis. The catheter should be replaced once in two days.

Dr. DAVENPORT then read a paper on

#### SOME FORMS OF DYSMENORRHOEA AND THEIR TREATMENT.

which is published on page 219 of this number of the JOURNAL.

Dr. ELLIOT said his experience with dysmenorrhoea had not been so favorable. He considered it only a symptom of a trouble which was not well understood;

many of the cases reported as cured, afterward relapse, and when dilatation has been done, the relief is often only temporary. Of the two forms, ovarian and obstructive dysmenorrhœa, very little is known except that with the first we get pain in the region of the ovaries at the time of menstruation and a leech on the cervix seems to relieve it, though no satisfactory explanation of the way in which this has been accomplished has yet been given. The second form, occurring generally with ante-flexion of the uterus, is more common; here dilatation does not always do good, and the trouble may be as severe when a large as when only a small sound can be passed. General treatment is of more service in these cases than local means.

DR. BOARDMAN laid special stress on dysmenorrhœa not being a disease but only a symptom of many conditions that often are found among women, especially those who are anæmic; where little clots are expelled with considerable pain.

In cases of so-called obstructive dysmenorrhœa, he thought there is often a sort of granulation tissue near the internal os, which causes a hyperæsthesia and increase of stricture; there did not seem to be any constant relation between the malposition of the uterus and the amount of pain.

DR. STRONG said that dysmenorrhœa was sometimes due to local conditions which could be removed; in married women with anteversion there was rarely any trouble, but in unmarried women, where the uterus was higher, it was more common. In many cases the use of the dilator gives relief, though it may not always be permanent, but the old method of cutting bilaterally has generally failed; although the application of a leech to the cervix, before the flow, may not answer much theoretically, yet it often gives great relief, and many women are able to get on very comfortably in this way.

DR. DAVENPORT, in closing, said that while he agreed with the remarks of Dr. Elliot and Dr. Boardman as to the generally unsatisfactory results of the treatment of dysmenorrhœa, and as to the importance of general treatment, yet the paper purposely left these facts out of consideration. The aim was to call attention to certain classes of cases where definite local causes could be found for the pain, by the removal of which a cure more or less permanent was effected.

It would be as unscientific to neglect these local conditions as it would be to subject all cases of dysmenorrhœa to operative treatment.

In these cases reported, no general treatment was needed for the causes found, enlarged and congested ovaries, stricture of the canal, ante-flexion and retro-flexion were sufficient to account for the pain, and the treatment of them brought about the desired result.

The object of the paper was to emphasize the importance of ascertaining the exact local condition in order that if any probable cause be found there for the trouble, it may be treated, in this way hoping to secure a more radical result than by drugs, and to point out certain simple operative and mechanical measures by which we may hope to attain this end.

—Mrs. Mulvaney (*the landress*). "Include, m'inn, an' it's miserable I am. I'm but jist on my feet wid the pain in me back, and Jimmy he's as bad off; he has a cough on um that sounds loike an impty bar'l. *Cough for the lady, Jimmy!*" — *Harper's Bazar*.

## Medical and Surgical Journal.

THURSDAY, SEPTEMBER 10, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY.

283 WASHINGTON STREET, BOSTON, MASS.

### THE INCREASE OF INSANITY AND ITS INADEQUATE TREATMENT.

IN a recent editorial, our esteemed contemporary, the *Boston Daily Advertiser*, published some statistics concerning the prevalence and increase of insanity in Massachusetts, and commented upon the care which the insane receive in the State hospitals. The general conclusion that the increase in the number of the insane has been exceptionally rapid in the last decade, is unquestionably true, although there is probably an error in placing it as high as sixty per cent. The census of the insane in 1875 was less complete than our present census, and a portion of the apparent increase is for that reason not real. The statement is also made that "the asylums, almshouses, and other institutions hold now not fewer than 5,700." This may, perhaps, be the whole number present in those institutions during the entire year, but must be about 1,200 more than they now contain.<sup>1</sup> The increase during the ten years of the insane coming under official notice seems, therefore, nearer forty than sixty per cent, a certain proportion of which percentage is accounted for by the fact that a larger part of the insane come under official notice now than formerly. This is bad enough and seems to illustrate the truth of some remarks made upon the curability of insanity. The writer then gives the proportionate number of physicians and attendants in some of the institutions, and questions whether these "asylums are not really mere places of detention instead of hospitals."

There is much force in this criticism, and we feel strongly that even the poor insane, who are not manifestly incurable, should have a hospital where each case could be better individualized, where their support should be more above a pauper standard, and where they would not be subjected to that blight of hopelessness which is bound, in some degree, to pervade an institution where the overwhelming majority of patients are manifestly incurable.

With an intention of doing what was humane and

<sup>1</sup> During the year ending October 1, 1884, there were committed to the State Board of Health, Lunacy, and Charity 4,645 persons under the official notice, "about 5,000, of whom all but two per cent were in Massachusetts when committed to our asylums," but 124 were removed from the State during the year. How many came into the State, or returned after removal, is unknown. *Report of 1884.*

best, however, this State has recently built expensive large hospitals, and thereby rendered such a system impracticable for the present, unless private benevolence shall accomplish it. This is unfortunate, but it is one of the least of the present misfortunes of our insane, and it is concerning these more crying evils that we wish to speak.

These are an overcrowding and a lack of classification that render proper hospital organization impossible. We speak in moderation of what is known to have been the condition of the Danvers hospital for more than a year past, when we say that, in spite of most excellent management on the part of the physicians, it has been a disgrace to the Commonwealth. That hospital receives a much larger number of new cases than any other in the State, and is equalled, in this respect, by very few in the world. It, therefore, cannot properly bear even a slight crowding that might not seriously inconvenience an unchanging chronic population. But the fact has been that, during the time mentioned, the number of patients has been so great that from one hundred to nearly two hundred have been obliged to occupy beds placed upon the floors of the wards at night, and to suffer corresponding inconveniences by day, personal privacy has been interfered with, proper classification has been made impossible, attendants and physicians have been wearied, and their time has been consumed in meeting unnecessary difficulties. Moreover, the patient who has been sent to the hospital "for rest and quiet," has the daily routine of his life filled with annoyances and irritations as preliminary to all treatment. Now it is to be considered that this crowded population does not consist of reasonable people, who have voluntarily come together for pleasure or profit, and can lessen their discomforts by mutual forbearance, but of those who have lost reason and self-control, and are forcibly detained by a power which they usually deem unjust.

It probably is true that many of the patients sent there bear these troubles easily, either because they are too much demented to appreciate them, because they have not been accustomed to comfortable homes, or because they belong to the less disturbed class of patients, who are not likely to irritate one another and who are able to adapt themselves to circumstances very much like sane people. But this does not lessen the suffering and injury of those who are appreciative and excitable, as is the case with a large proportion of those who present the best prospect of restoration to health, and to whom the treatment of a hospital can be most valuable. It is a disgrace to the State that the officers of its hospitals are obliged to state that they have no place where these patients can receive the care and treatment which their condition demands.

That this evil exists as it does is not wholly a necessity arising from the increased number of the insane, but is partly due to a lack of any system of selection of cases which need the special structural provision of our hospitals for the insane for treatment in them, and of proper provision for those who do not, elsewhere. The function which the lunatic hospital

is now made to perform is not only that of caring for those who are dangerous to society and of furnishing remedial treatment for mental disease, but it is used as a convenient dumping ground for all cases of degenerative nervous diseases attended with mental failure, which are disagreeable to care for elsewhere, or whose care costs more than \$3.25 per week. This class is very large in the crowded population of eastern Massachusetts, and if all the feeble, broken-down cases, not needing other care and nursing than that which could be properly furnished in cheap buildings with no special structural provisions, were removed from the Danvers Hospital, its overcrowding would be sufficiently relieved to enable it to do proper remedial work for those who do need the special and expensive structural arrangements of a hospital for the insane,—a work which it is impossible for any staff of medical officers to accomplish satisfactorily under the existing circumstances.

Boston, having a larger number of this class than any other city in the state, is most grievously at fault, in that it makes no adequate provision for their permanent care, and in that it has no suitable reception hospital with facilities for temporarily treating patients with mental symptoms, until there is opportunity to decide whether they are suffering from insanity proper, or from the delirium of acute disease or alcoholic poisoning, or other conditions rendering commitment to an insane asylum unwise or improper.

Such hospitals exist in other large cities, and one here would not only do much to prevent the hasty commitment of improper cases but would furnish a place other than the Tombs for the temporary care of insane persons awaiting commitment. We are aware that both the City Hospital and the Boston Lunatic Hospital do some of this work, but the former has no proper facilities for it, and the latter is already overcrowded by its regularly committed patients.

For those feeble and demented patients who are a state charge, and for those belonging to the smaller towns, which cannot give them proper care, it will be necessary for the state to provide cheap buildings adapted to their needs, probably best in connection with one of the Hospitals in the eastern end of the state. The very pressing need of such provision was fully represented to the last legislature, but no action was taken by it.

#### SMALLPOX IN CANADA AND MASSACHUSETTS.

AFTER a period of comparative immunity from smallpox throughout the whole of North America, the disease has assumed the character of an epidemic at Montreal. Following a small localized outbreak in Ontario last fall, it appeared at Montreal in April, but not until mid-summer did it become unusually prevalent, thus taking a course contrary to its usual characteristic as a cold weather disease.

The population suffering most at Montreal are the Canadian French, among whom, ignorance and neglect of the first principles of sanitation are common traits

of character. That portion of their number which annually swells the tide of emigration across the border is not above the average in the same characteristics. Hence it follows, in consequence of direct communication with the Dominion of Canada by several lines of railroad travel, that many of the localized outbreaks of smallpox in Massachusetts in the past decade may be traced directly to the French Canadian immigrant.

This fact began to be apparent in the great epidemic of 1872-1873, when more than 6,000 cases and 1,300 deaths occurred in Massachusetts.

In the third report of the State Board of Health (1872) it was stated that "Lowell and Holyoke have a large population of foreigners including many French Canadians. These people are notoriously perverse in refusing vaccination, and when sick with smallpox, conceal the disease."

Since that time other cities and towns have received large accessions to their population from the same source.

The cases which occurred in Holyoke in 1883, were among unvaccinated French Canadian immigrants, and the same was also true of the town of Holden in 1884. In the town of Spencer in 1873, a French Canadian physician inoculated fifty-two children in the French settlement of that town with virus which proved to be that of smallpox.<sup>1</sup>

During the past week three children were taken ill with smallpox in a French Canadian family in Fall River, two of whom have since died. None of them had been vaccinated and the disease was undoubtedly brought from Montreal by the mother. These are but a small portion of the cases which might be cited.

With these facts in view there is special need of vigilance on the part of all local Boards of Health, whom the Statutes have charged with the special duty of protecting the public. Adequate power is given them for enforcing the statutes, and such power should be exercised. There can be no doubt that smallpox can be totally excluded from any community, or at least confined to the first cases by proper sanitary precaution. The following cardinal points should be kept in view by all local authorities having charge of the public health.

(1) As far as possible guard against the introduction of the disease.

(2) Vaccination and re-vaccination.

(3) Isolation and non-intercourse with the sick.

(4) Disinfection.

Dependence should never be placed upon the latter (disinfection) to the exclusion of vaccination, since there is not the slightest evidence that smallpox is in the strict sense a filth disease. No amount of filth will originate smallpox, and although *eteris paribus*, habits of cleanliness will in a measure prevent contagion, a community of unvaccinated people who are scrupulously clean, would undoubtedly fare very much worse in the face of an epidemic of variola, than a thoroughly vaccinated community of notoriously filthy habits.

It should be distinctly borne in mind that every unvaccinated person in a community is a source of danger, whose presence should not be tolerated.

The public health is paramount to private interests and no one has the right to endanger the lives of his fellows by means of his own neglect.

The last Legislature, in common with its predecessor, refused to enact a law providing for an independent Board of Health in every town, and hence in a town where no such board exists, the Selectmen constitute the Board of Health. It is plain that such boards, elected in an *ex officio* manner and without the slightest fitness for the duties pertaining to public health, are often wholly incompetent to cope with so formidable an enemy as an epidemic of smallpox.

It is in such towns that the Statutes relative to notice of cases by physicians and householders, and also the law relative to the exclusion of unvaccinated children from the public schools are often disregarded. The careful and thorough enforcement of each of these laws is a matter of the greatest importance. The latter being one of our strongest safeguards against the disease, while a neglect of the former is both dangerous and criminal.

The following quotation from the pen of Dr. Geo. Derby, the first Secretary of the State Board of Health of Massachusetts, has lost none of its force in the years that have elapsed since it was written in 1871.

"We may speculate about the possibility of the potency of vaccine being exhausted in the human family, we may be surprised to find that people with good vaccine scars sometimes have smallpox, we may dispute as much as we please about the average period when re-vaccination may be considered a prudent safeguard, we may even conjecture that other diseases than that of the cow may be communicated by humanized vaccine, we may turn the vaccination question with ingenious skill, so that its many facts shall reflect a multitude of curious lights, and after all we find that we rest in a security against the horrid pestilence unknown to former generations."

An examination of the present condition of affairs in Montreal by the officers of the State Board of Health of New Hampshire, shows that the statements of the Health department of Montreal do not represent the magnitude of the epidemic, which embraces not only the city, but also the out-lying municipalities; and that the reported figures must be at least doubled to fully state the death rate. As the result of their observations, they state that it is their opinion that the Canadian authorities cannot handle the epidemic within their own borders, much less assist in any marked degree in keeping the disease out of the New England States, and they accordingly, in an address to the National Board of Health, reiterate the above facts, recall the powerlessness of a State Government in international matters, and state their belief that it is the duty of the National Government to take immediate action in this matter.

<sup>1</sup> State Board of Health Report, (1873), p. 513.

## MEDICAL NOTES.

—The Prefect of Police has issued a decree that the remains of the bodies dissected in the dissecting-rooms of the Paris School of Medicine shall be cremated in the apparatus for the purpose. The Prefect of the Seine, the Director of the Assistance Publique, and the Dean of the Paris Medical Faculty, have been informed of this decision.

—Hydrate of chloral has, according to the *London Medical Record*, been successfully employed instead of cantharides for blisters. For this purpose, powdered chloral is sprinkled on previously slightly warmed adhesive plaster. Vesicles are raised by it in about ten minutes. The advantages of this blister over other kinds are, rapid and perfectly painless action, and absence of any troublesome effect usually caused by cantharides.

—The proud distinction of having the meanest man on record is claimed for Oakville, Can. His wife was ill and the doctor prescribed wine. As it was not easily found, the doctor sent some from his private stores. The woman died. When the doctor's bill came in the broken-hearted widower lodged a complaint against the physician for selling liquor contrary to law.

—Dr. Wingate reports (*Medical Times*) eight cases of united fractures in teeth, from Carbondale, England,

where there is a large class of miners, amongst whom accidents are common. As these teeth were all extracted on account of the pain and discomfort caused by their distorted shape, it is probable that united fractures in teeth are much more common than has been supposed, for these teeth represent the failures only; the successful cases, not giving trouble, were never recognized.

—A lay exchange, speaking of the recent cold snaps, says it not only struck the corn belt of the West, but in the Southern States is striking below the belt.

## Correspondence.

## A PHYSICIAN WANTED.

A correspondent sends the following, which may be of interest to some of our younger readers: "I take the liberty of writing to you to say that where I spent my vacation, in the town of Tiverton, R. I., a physician is very much needed. I send this to you as an item of information. I know that the people residing at Tiverton Four Corners have to send six miles for a doctor, and those near the stone bridge or depot telephone several miles away to Fall River. If you know or hear of a physician who wants a country practice, he can address Mr. Isaac Brown, Tiverton, or Rev. Mr. Arnold, at Tiverton Four Corners, R. I., either of whom will give information respecting the matter."

Deaths reported 2,621: under five years of age, 1,433; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 702, diarrhoeal diseases 123, consumption 315, lung diseases 120, diphtheria and croup 80, typhoid fever 65, malarial fevers 37, whooping-cough 28, cerebro-spinal meningitis 22, scarlet fever 17, measles nine, puerperal fever seven, erysipelas five. From malarial fevers, New York thirteen, Brooklyn seven. From malarial fevers, New York three, Chicago two, Philadelphia, District of Columbia and New Haven one each. From whooping-cough, New York 16, Brooklyn six, Philadelphia, Chicago and Baltimore three each, District of Columbia two, Fall River one. From cerebro-spinal meningitis, Fall River four, Chicago eight, New York three, Philadelphia, Boston, District of Columbia, Worcester, Springfield, Taunton and Brockton one each. From scarlet fever, Brooklyn seven, Boston three, New York, Philadelphia and Springfield two each, District of Columbia one. From measles, New York and Chicago two each, Philadelphia, Brooklyn, Boston, Baltimore and New Haven one each. From puer-

peral fever, Boston three, Chicago two, Philadelphia and Cincinnati one each. From erysipelas, New York and Baltimore two each, Brooklyn one.

In 113 cities and towns of Massachusetts, with an estimated population of 1,413,397 (estimated population of the State 1,355,540), the total death-rate for the week was 19.47 against 23.70 and 23.27 for the previous two weeks.

In the twenty-eight greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending August 8th, the death-rate was 21.8. Deaths reported, 3,715; infants under one year of age 1,491; acute diseases of the respiratory organs (London) 184, diarrhoea, 628, measles 109, whooping-cough 94, fever 53, scarlet fever 35, diphtheria 26, smallpox (London) five. The death-rates ranged from 13.2 in Wolverhampton to 32.2 in Leicester; Birmingham 17.7; Bradford 23.8; Hull 17.1; Leeds 23.2; Liverpool 24.9; London 22.0; Manchester 24.3; Sheffield 21.5; Sunderland 23.7; Edinburgh 15.6; Glasgow 24.6; Dublin 19.8.

Massachusetts towns								

Deaths reported 2,492: under five years of age, 1,127; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 716, diarrhoeal diseases 138, consumption 317, lung diseases 148, diphtheria and croup 87, typhoid fever 61, whooping-cough 39, malarial fevers 34, scarlet fever 21, cerebro-spinal meningitis 13, measles 10, erysipelas seven, puerperal fever six. From whooping-cough, New York 16, Brooklyn seven, Philadelphia six, Chicago three, Baltimore and New Orleans two each, Providence, New Haven and Nashville one each. From malarial fevers, New York four, New Haven and Charleston one each. From scarlet fever, New York five, Brooklyn and Baltimore four each, Chicago three, Philadelphia two, Boston, Nashville and Fall River one each. From cerebro-spinal meningitis, Chicago four, Philadelphia and Worcester three each, New York two, Fall River one. From measles, New York six, Chicago two, Brooklyn and Boston one each. From erysipelas, Brooklyn three, New Orleans two, New York and New Haven one each. From puerperal fever, Chicago three, New York, Brooklyn and Boston one each.

In 112 cities and towns of Massachusetts, with an estimated population of 1,426,641, (estimated population of the State 1,355,540), the total death-rate for the week was 18.27 against 19.47 and 23.70 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending August 22d, the death-rate was 19.7. Deaths reported 3,343; infants under one year of age 1,178; acute diseases of the respiratory organs (London) 165, diarrhoeal diseases 137, whooping-cough 87, measles 84, fever 41, scarlet fever 35, diphtheria 18, smallpox (London) four. The death-rates ranged from 10.9 in Bolton to 30.1 in Preston; Birkenhead 18.5, Birmingham 20.7, Bradford 22.7, Hull 22.6, Leeds 19.4, Leicester 22.2, Liverpool 25.0, London 18.8, Manchester 21.4, Sheffield 24.2, Sunderland 20.0, in Edinburgh 17.1, Glasgow 24.1, Dublin 25.5.

For the week ending August 15th in the Swiss towns there were 34 deaths from diarrhoeal diseases, consumption 21, lung diseases 14, whooping-cough five, smallpox two, typhoid fever two, measles one. The death-rates were at Geneva 6.2, Zurich 3.9, Basle 21.2, Bern 20.7.

The meteorological record for two weeks ending August 29th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 29, 1885, TO SEPTEMBER 4, 1885.

MAGRIDER, D. L., lieutenant colonel and surgeon. Granted leave of absence for fifteen days. S. O. 201, A. G. O., September 3, 1885.

MIDDLETON, PASSMORE, major and surgeon. Assigned to duty as attending surgeon at these headquarters, vice major J. V. D. Middleton, surgeon, hereby relieved. S. O. 131, Department of the Missouri, August 26, 1885.

CRONKHITE, H. M., captain and assistant surgeon. Relieved from duty at Fort Reno, Indian Territory, and assigned to duty as post surgeon at Fort Hays, Kansas. S. O. 129, Department of the Missouri, August 26, 1885.

GHARRI, ALFRED C., captain and assistant surgeon. Assigned to duty as post surgeon at Boise Barracks, Idaho Territory. S. O. 112, Department of the Columbia, August 22, 1885.

DAVIS, WILLIAM B., captain and assistant surgeon. Having reported for orders from leave of absence, assigned to duty at Fort Porter, New York, as post surgeon. S. O. 183, Department of the East, August 28, 1885.

POWELL, J. L., captain and assistant surgeon. Relieved from temporary duty at Fort Leavenworth, Kansas, and assigned to duty as post surgeon at Fort Lyon, Colorado. S. O. 128, Department of the Missouri, August 25, 1885.

EVANS, JOHN M., captain and assistant surgeon. Assigned to temporary duty at Camp of Competitors at Creelwood, New York, arriving not later than September 4, 1885. S. O. 58, Department of the Atlantic, August 31, 1885.

MCOW, W. D., first lieutenant and assistant surgeon. Assigned to temporary duty at the camp of the troops near Kiowa, Kansas. S. O. 128, Department of the Missouri, August 25, 1885.

KENDALL, WILLIAM P., first lieutenant and assistant surgeon (recently appointed), to report in person to the commanding general, Department of California for assignment to duty. S. O. 201, A. G. O., September 3, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY, DURING THE WEEK ENDING SEPTEMBER 5, 1885.

STEWART, HENRY, surgeon. Leave of absence extended one year from October 15, with permission to remain abroad.

STERLE, JOHN M., passed assistant surgeon. Detached September 1 from Constellation, and report for duty at Naval Academy, Annapolis, Md.

BRIGHT, GEORGE A., surgeon. Detached September 1 from Constellation and wait orders.

DICKSON, S. H., passed assistant surgeon. Ordered to Naval Academy, Annapolis, Md., as relief of Passed Assistant Surgeon A. A. Austin.

FITTS, HENRY B., assistant surgeon. Detached from coast survey steamer "Gedney" and wait orders.

AUSTIN, A. A., passed assistant surgeon. Detached from Naval Academy, Annapolis, Md., and ordered to coast survey steamer "Gedney" to relieve assistant surgeon H. B. Fitts.

#### FERRATA.

In last week's issue of the JOURNAL, p. 228, l. 7, the word multiparous should read nulliparous.

#### BOOKS AND PAMPHLETS RECEIVED.

Fourth Annual Report of the State Board of Health of the State of New Hampshire for the Fiscal Year ending April 30, 1885.

A Treatise on Epidemic Cholera and Allied Diseases. By A. B. Palmer, M.D., L.L.D., Professor of Pathology, Practice of Medicine and Clinical Medicine in the College of Medicine and Surgery in the University of Medicine.

Diseases of the Tongue. By Henry T. Butlin, F.R.C.S., Assistant Surgeon and Demonstrator of Practical Surgery and Diseases of the Larynx, St. Bartholomew's Hospital.

Forty-Fourth Annual Announcement of the St. Louis Medical College. Seventh Street and Clark Avenue. Winter Session 1885-86 and Catalogue for 1884-85.

## Original Articles.

IS CRANIOTOMY UPON THE LIVING FETUS EVER JUSTIFIABLE?<sup>1</sup>

BY ROBERT B. DIXON, M.D., OF BOSTON.

I WOULD say in the beginning, that this paper is from a purely medical and non-ecclesiastical point of view; and in no way have I, in dealing with the subject, touched upon it from an ecclesiastical standpoint.

An attempt to look through the works that have been published during the past fifty years upon the justifiability of the operation of craniotomy upon the living fœtus, taught me that the contributions upon this subject were indeed numerous, and that the topic had been dwelt upon by men eminent the world over. Still this subject, important as it is, remains in an unsettled condition. It is not with the idea that I can add anything of value to the subject that I deal with it; but I do so more especially because in a paper recently read by Dr. Basey, of Washington, the strong statement, which is the title of the article, is made, that "Craniotomy upon the Living Fœtus is not justifiable." What I shall attempt in this paper will be to collect such strong conclusions as will clearly show that craniotomy, in certain instances, is vindicable by reason, and, in these cases, is the only operation that can be justifiably done.

The question of destroying a living fœtus is a most serious one, and every means should be taken to obviate the necessity for the operation. In large cities, where there are usually two or three practitioners skilled in the various operations of abdominal section, where trained assistants and nurses are at hand, and where all the instruments and appliances necessary to the operation can be obtained at short notice, then, perhaps, in most cases where craniotomy would usually have been performed, abdominal section might be chosen if the woman is in a suitable condition to undergo the operation; that is, labor has not commenced or is just starting, the woman is in no way exhausted, and there is positive evidence that the child is alive. Supposing, however, that a country practitioner is called to a woman in labor, and, from some one of the many obstacles which may exist, he finds it impossible to deliver the woman *per vaginam*, without diminishing the diameters of the child's head, what is he to do? Would it be justifiable for him to attempt the difficult operation of abdominal section, an operation which, in all probability, he has never seen performed, or knows anything more about than what can be learned from text-books? One might say that he should send for some practitioner who can do the operation; but the delay thus necessitated would, with little doubt, result in the death of the child, and get the woman into such an enfeebled condition, that her life would also be imperilled.

The obtainable statistics of recoveries after the various methods of abdominal section, for removing a living child, are those computed by men, who, although they but rarely open the abdominal cavity to remove a fœtus, are almost daily removing the various kinds of tumors by abdominal section. Supposing the general practitioner should try his hand at this operation, an operation which could hardly be called for more than once or twice during his lifetime, how then would the statistics stand if they could be collected? In all probability, if the woman did not die from hemorrhage dur-

ing the operation, she would hardly survive the after-coming shock and exhaustion, and very likely in such cases as these, the child would be extracted in a moribund condition.

That craniotomy, an operation that existed previous to the time of Hippocrates, has been time and again performed when it ought not to have been, in cases which, with the present knowledge of obstetrical surgery would be treated differently, there is not the least doubt. Many fetal lives that were destroyed in cases of slightly contracted pelvis, or when the diameters of the fetal head were a little above the average, or there was premature ossification of the bones of the head, might have been saved by the forceps or version. There are but few eminent obstetricians with a large consultation practice, who have not been summoned by a brother practitioner to do craniotomy, and found, after thorough examination, that there was a possibility of extracting a living child by version, and making the attempt, have succeeded in so doing. In our city there are several obstetricians who have had experiences of this kind.

Now, right here comes up the important subject of version, which will save many lives, and in slightly contracted pelvis, obviate puncturing the fetal head till it becomes an absolute necessity. For many years Dr. W. L. Richardson, of Boston, has strongly advocated version in cases of slightly-contracted pelvis, where failure in delivery has resulted from the application of the forceps. He has had marked success in many cases which would have come to craniotomy if version had not proved beneficial. If turning can be accomplished in slightly-contracted pelvis with a good degree of success, ought it not to be the procedure in all such cases?

There is a good probability, if the operation is done early and skillfully, that a living fœtus may be extracted. If the head cannot be removed, then craniotomy can be done; and it has been shown that craniotomy upon the after-coming head is not as difficult a maneuver as has been thought. The successful termination, by version, of many of these cases which the attending physician has made up his mind must come to craniotomy, strongly brings this operation forward as a measure which is, indeed, sound and scientific.

Would it be considered good judgment to do Cesarean section or one of its substitutes, for the removal of a child with a hydrocephalic head? I should say not. Supposing a physician is called to a woman in labor with good pains. Upon examination, and the lapse of time, he learns that for some unknown reason the head of the child does not descend. The woman is etherized, and the operator's hand inserted into the vagina and through the cervix, so that the child's head can be taken into it and thoroughly examined. The introduction of the hand will demonstrate to a practitioner of even moderate experience, the presence or absence of pelvic contraction of any moment. If it is determined that the pelvic diameters are normal, or nearly so, and that the child's head is hydrocephalic, would any one say that craniotomy ought not to be done and is the only suitable operation? The woman's pelvis is all right, as it would most likely be, and the child can be removed after the head is perforated, with less trouble than by forceps or version when these operations are called for. The risk of the soft parts of the woman being injured by pressure, as in cases of severely contracted pelvis, is absent, and the percentage of recoveries after the operation could not be otherwise than very large.

<sup>1</sup> Read before the Section for Obstetrics and Gynecology, of the Suffolk District Medical Society, April 15, 1885.

Most certainly, in a case of this kind, abdominal section in none of its varieties is justifiable; for most assuredly, the death of a diseased fetus whose chances, if delivered safely, of survival are the slenderest, cannot be compared with the recovery of a woman, healthy in all her parts, and who in every way is constituted to continue having children, which she is very likely to do.

A physician in attendance upon a woman who cannot be delivered other than by craniotomy or abdominal section, who, in no way, is sufficiently familiar with the operation of opening the abdomen, and who, if he made the attempt, would probably lose the mother and quite likely the child also, could hardly be considered as acting in a sound manner in attempting anything of the kind. If the operation is not done, then craniotomy is the only resort; otherwise, both the mother and child will be lost.

A few statistics compiled from the various operations which have been performed by eminent men for the removal of the child by Cæsarean section, or some one of its substitutes, laparo-elytrotony and Porro's operation, will be of the greatest value. The results from these operations during the past few years, under the improved and more skilful methods of operating, have been most pronounced. Out of something over 1,500 tabulated cases of Cæsarean section, occurring in England, Germany, France, Belgium, Italy and America, the average mortality was fifty-three per cent. Dr. Harris, in the *Obstetrical Journal* for February, 1872, reports seventeen cases which were operated upon the first day of labor. Out of these 73½ per cent of the women recovered and 86½ per cent of the children were saved. Of all the cases operated upon in France for fifteen years up to 1861, of those operated upon early, while the strength of the patient was still good, 81 per cent of the women recovered; where the patient, however, was in a state of exhaustion when the operation was commenced, only 19 per cent recovered. Up to 1876, when Späth<sup>2</sup> operated, every Cæsarean case in a century had proved fatal in the Lying-In Hospital in Vienna, and a like fatality had followed for nearly as long a period at the Maternité at Paris, till Professor Tarnier operated in 1879.

Dr. R. P. Harris,<sup>3</sup> of Philadelphia, tabulated 59 cases of Cæsarean section occurring in the United States, between 1822 and 1870, in which there were thirty-one recoveries and twenty-eight deaths. The results to the children were that twenty-six were born alive, thirty-two were lost, and the result to one was not stated. The prevailing causes of death in the women were exhaustion and peritonitis, and in the children the causes assigned were principally long labor and some operative procedure as craniotomy.

Of eleven cases of Cæsarean section, occurring during the past few years, that I have tabulated, nine women and eight children were saved. Most of these operations occurred very early. Winckel has performed fourteen Cæsarean operations, and saved six mothers and nine children. Previtali, of Italy, lost seventeen out of nineteen cases. But two of twenty-seven were saved in Naples, and Dr. Belluzzi had twelve operations, in one of which the mother recovered. Späth,<sup>4</sup> of Vienna, has reported four cases of Cæsarean section which were under his observation between 1852 and 1871, all of which ended fatally. He considers hemorrhage the chief source of danger.

Dr. Harris quotes the comparative results of the Cæsarean operation in the two countries, as follows: Great Britain and Ireland, cases, 106; fatal, 88; children saved, 60. United States, cases, 60; fatal, 28; children saved, 27. Dr. Harris' twenty-four cases reported in the *American Journal of Medical Sciences* for April and July, 1878, and January, 1879, in which the operation was performed within twenty-four hours from the beginning of labor, show that of these six died and eighteen were saved, about 75 per cent. M. Pehan Du-fellay has shown that 81 per cent of women operated upon early and before the strength was exhausted, recovered.

Lusk says that Cæsarean section is chiefly justifiable in cases in which craniotomy and the delivery of the child by the natural passages involve the life of the mother in still greater peril. It is indicated, therefore, in extreme degrees of pelvic contraction, in the case of solid tumors which encroach upon the pelvic space, and in advanced carcinomatous degeneration of the cervix.

Statistics on Porro's operation give beneficial results. Champimiere<sup>5</sup> reported four cases in which two women and all the children were saved. In 1879, Dr. Harris tabulated 37 cases of Porro's operation with 17 recoveries and 20 deaths. Späth considered the results of Porro's operation as very promising. The operation is considered as safer than Cæsarean section, and also safer than craniotomy in extremely contracted pelves. It is being rapidly adopted on the continent, and with a marked degree of success.

In the *American Journal of Medical Sciences*, April, 1885, is a review of the report of Dr. Clement Godson, of all of the Porro's operations up to the beginning of the year 1885—164 cases in all. There were 109 cases of Porro's, many of them very unfavorable, with 46 recoveries. Müller's modification was used in 41 cases, with 21 recoveries. From the 164 women, 166 children were extracted; of these, 129 were living and 37 were dead, or moribund. Dr. Godson thinks it but just to the operation to reduce the 164 cases to 147, by excluding three moribund cases operated upon to save the children, and fourteen in which the stump was dropped in, proving fatal in ten cases. Those cases operated upon in hospitals have done better than those in private houses. When the patient is prepared beforehand, and the time has been carefully selected, the results from the hospital operations are very encouraging.

Of 134 cases of Porro's operation reported by Dr. Godson<sup>6</sup> in 1884, the maternal mortality was fifty-five and ninety-seven hundredths per cent. Carl Braun had a mortality of forty per cent, while Späth and Gustave Braun had a mortality of fifty per cent.

Laparo-elytrotony has given better results than Cæsarean section, for by it the dangers of peritonitis and shock are reduced to a minimum, and there is not the likelihood of septicæmia showing itself. There is, however, great risk of hamorrhage from the vascular supply to the vaginal walls, and also the risk of vesico-vaginal fistula. Garrigue<sup>7</sup> says, "The incision of the vagina may be made almost safe by using the cautery, and by tearing instead of cutting." The earlier operations by Jorg and Baudelocque, were abandoned on account "of the severe hamorrhage, and the children were removed by Cæsarean section in order that their

<sup>7</sup> *Gynecol. Journ.*, p. 229, 1878.

lives might be saved." Of eleven cases collected by Kinshead,<sup>8</sup> of Dublin, seven died, giving a mortality of 63.3 per cent. In two of these the operation was abandoned and Casarean section was substituted, while in a third, the operation was complicated by the ligation of the internal and common iliac arteries. Of the remaining eight cases, four died, giving a mortality of fifty per cent. The death in some of these cases cannot be attributed to the operation. In the case of Dr. Thomas, in 1870, the woman had pneumonia, and was in an almost moribund condition at the time the operation was commenced. Two cases reported by Dr. Skene and one by Hime were also in a severe state of exhaustion.

Barnes gives, under three heads, the following indications for the performance of craniotomy:

*First.* Such contraction of the pelvis, or soft parts, as will not give passage to a live child, and where forceps and version are of no avail. These may be due to distortion of the pelvis, which is most frequent at the brim; to tumors—bony, malignant, or ovarian—encroaching upon the pelvic cavity; to growths, fibroid or malignant, in the walls of the uterus; to cicatricial atresia of the vagina or cervix; to extreme spasmodic contraction of the uterus upon the child, forbidding forceps or turning; where obstruction in pelvic contraction ranges from 3.25" maximum to 1.50" minimum.

*Second.* Cases where the obstruction is due to the child, as face presentation, locked twins and hydrocephalic head.

*Third.* Condition of danger to the woman, rendering it expedient to deliver as rapidly as possible. Some cases of rupture, convulsions, hemorrhage, or great exhaustion, where delivery is urgent and the cervix undilated.

The mortality in craniotomy has been shown to be about one in five, but it would not be as high as this even if the operation was not attempted in cases where the antero-posterior diameter of the pelvis is below two and a half inches. The high percentage of recoveries after recent Casarean operations comes from the cases being selected, and from the operation being performed upon the woman during the early hours of labor, or previously to labor beginning, when the patients are in a sound condition and free from exhaustion. The opponents of craniotomy in their collection of statistics do not use this same method in the selection, for tabulating, of craniotomy cases, but take all the cases together irrespective of the time of the operation or the condition of the patient. If statistics were obtainable upon those cases of craniotomy that were performed early, the patient being in a good condition, then the percentage of recoveries after craniotomy would be very much larger.

Recent craniotomy statistics are those of Dr. Adolph Merkel,<sup>9</sup> of one hundred craniotomies at Leipzig from 1877-1882, with a mortality of eight per cent. Excluding a case of ruptured uterus, determined before the operation, and the mortality would have been but six per cent. Biber,<sup>10</sup> of St. Petersburg, did not lose a single woman out of thirty-two craniotomies performed from 1872-1877. Spiegelberg had a mortality of sixteen per cent in fifty-eight cases. Rokitsansky,<sup>11</sup> Jr., published an account of fifty-two successful craniotomies occurring in Braun's wards.

In most of the instances where craniotomy is performed, the child is dead before the operation is called for. Generally, other operations for extraction are continued till the last moments of the child's life. Very likely the forceps will be first applied, but failure with these will cause the practitioner to attempt version. He may be successful in turning the child, but not in extracting the head. If not, then there is no other alternative than craniotomy. In cases where the pelvis is not contracted much, the danger to the mother, if she is in no way exhausted when the operation is begun, is very slight. If a woman has once had craniotomy performed, she should be especially urged to have premature labor induced if she should become pregnant again, and if there is but slight narrowing of the pelvis she may give birth to a viable child.

Dr. Goodell<sup>12</sup> considers craniotomy justifiable in certain instances, for living children are sometimes born afterwards. He does not consider it wise to wait till the child is dead, but operates as soon as he thinks the operation called for. He believes in leaving the question of propriety of operating upon a sick woman to herself and her husband, and recommends that physicians will consider the question in a more logical manner, if they will bring it home to their own firesides.

The dangers from craniotomy are much less than from Casarean section, Porro's operation, or Laparotomies, excepting in cases of very contracted pelvis. In cases that have gone on for some little time, the woman may be past recovery before the operation is commenced.

Dr. Kidd<sup>13</sup> in the discussion upon a paper on "Craniotomy and its Alternatives," read by Dr. Kinshead before the Dublin Obstetrical Society, said: "Authors variously mention antero-posterior diameters of from three and a half to three inches or less, as the smallest through which a living child can pass. At the bedside I believe this difficulty can never arise, where you can have opportunities of comparing the size of the head lying above the pelvis itself, and can apply the forceps once or twice, besides having the assistance of a person in whose judgment you have confidence. If we are once satisfied, after due and careful trial, that we cannot bring the head through in an unimpaired condition, and that delivery can be easily and safely effected by the operation of craniotomy, I maintain that it is our duty to lessen the head, and to deliver the woman. I say this, viewing the question from a purely obstetric point of view, which is the only one that we here, and in this Society, are called on to consider."

In addition to Dr. Kidd's recommendation, I should say, if the woman is exhausted, it would be better to attempt version in these cases if there should be failure in delivery by means of the forceps, before doing craniotomy. If, for some reason, it was found to be impossible to turn the child, then craniotomy might be done. But if the child can be turned, it might be extracted where delivery by the forceps had failed, and if it could not be extracted, then the after-coming head can be perforated. Dr. Kidd does not consider it our duty, even with so narrow an antero-posterior diameter as two inches, to perform Casarean section.

Dr. E. B. Sinclair, president of the Dublin Obstetrical Society, said, we should not cut open a woman with a slightly contracted pelvis, when we are unable

to deliver with the forceps, but craniotomy should be done, by which operation she would have hardly any chance of losing her life. He further says, "But when we come to cases of extreme narrowing, where craniotomy cannot be performed without lacerating the parts, and where we find from examination that the operation would be so seriously dangerous to the woman that in all probability she would die under or after it, then Cæsarean section ought to be performed in preference to craniotomy."

Dr. Parish, of Philadelphia, said, craniotomy does not require so much skill as the Porro or Cæsarean operations. In these latter, not only is a trained surgeon required, but also several skilled assistants; but the delivery of a woman has often to be accomplished by a single physician remote from help. An operator may perform craniotomy without assistance as successfully as with it. A practitioner who has scruples against doing craniotomy when justly called for, and who for many reasons is not so situated as to do Cæsarean section, or have it performed, should also have some scruples about leaving a woman to die undelivered.

With the present knowledge of Cæsarean section, with increased experience in the time of choosing the operation and the greater skill with which it can be accomplished, it would seem that this operation should be chosen early in labor in those cases of very narrow pelvis, where the woman is still in a good condition, and is not as likely to suffer from hemorrhage as she would be if exhausted from a long and tedious labor. If, for some reason, in those cases of very narrow pelvis, the labor has been prolonged, and the woman is tired out and exhausted, then the uterus and ovaries should be removed, or, perhaps, Laparo-elytrotony be done, there being less risk of severe hemorrhage than from Cæsarean section.

If the contraction of the pelvis is not excessive, then craniotomy should be done.

Craniotomy is justifiable, according to the most prominent obstetricians throughout the world, when there is a failure by version or forceps in extracting the child, when the woman is exhausted, and when the pelvic diameters are such that only a mutilated fetus can be drawn through. The woman's chances are much better after craniotomy for slight narrowing of the pelvis, and the percentage of recoveries is very large. It is a difficult matter in the choice of operations to determine, with any degree of accuracy, the pelvic diameters while labor is going on. Craniotomy should be performed, however, if the operator feels reasonably sure that the diameters are above 3 by  $2\frac{1}{2}$  inches.

Prof. Isaac E. Taylor,<sup>14</sup> in a paper read before the New York Academy of Medicine in 1876, says that Cæsarean section should not be performed where the contractions or deformity of the pelvis are less than  $1\frac{1}{4}$  inches antero-posterior, and  $2\frac{1}{2}$  to 3 inches in the transverse diameter, unless some other complications or circumstances exist or presents.

Lusk says: "If the life of the mother is at stake, and the sacrifice of the child is necessary to her preservation, few would dispute, at the present day, the superiority of the mother's claim to existence."

My investigations lead me to form the following conclusions:

(1) It is our duty to save the child as well as the

mother, when in each individual case it is practicable and possible.

(2) Craniotomy should be performed when the child cannot be extracted by forceps or version; the woman is in a state of exhaustion, the pelvic diameters are above  $2\frac{1}{2}$  by 3 inches, the case has dragged along for many hours, or perhaps for several days, and it is the wish of the woman and her husband that the operation should be done. In a case of this kind, it would be wise to attempt version first, and then, if necessary, perforate. If the woman's health is not sound, her pregnancy is complicated by heart disease, phthisis, or uterine cancer; then it is a very difficult point to decide whether craniotomy or Cæsarean section should be performed, and this question can only be decided upon the merits of each case.

(3) When the conjugate diameter is below 2 or  $2\frac{1}{2}$  inches, or there is some organic obstruction that cannot be pushed out of the way or removed by tapping, as an ovarian tumor, then, especially if early, Cæsarean section or one of its substitutes should be performed. The results from Porro's operation and Laparo-elytrotony are so encouraging, that in many cases one of them might be selected instead of the old Cæsarean section.

(4) When the antero-posterior diameter is above  $2\frac{1}{2}$  inches, forceps may be tried, and, if unsuccessful, then version should be attempted; and if the operator is unable to extract the after-coming head, he should perforate it. If in any of these cases the malformation is recognized sufficiently early, then the induction of premature labor is called for.

(5) Under the most extenuating circumstances only, should craniotomy be attempted when the antero-posterior diameter of the pelvis is less than  $2\frac{1}{2}$  inches.

(6) Craniotomy upon the living fetus is justifiable when the practitioner is not familiar with abdominal section; when he is remote from help and has not trained assistants, or the proper instruments required for the latter operation; in those cases where it is the desire of the woman that it should be done in preference to abdominal section; when the woman is unconscious from disease or drugs; when the child's life has been imperilled by forceps or version, or the child is deformed or not viable; in cases where the use of the forceps has been delayed, the soft parts have become badly swollen and the head is impacted; when the uterus is in a state of tonic contraction, so that version cannot be done, and so much force is necessary in the application of the forceps that the life of both the mother and the child will be greatly endangered; when there is uncertainty as to whether the child is alive or dead, and longer delay will expose the mother to great peril; when there is but slight narrowing of the pelvis, after forceps and version have been tried, for the woman may have a live child afterwards, at term or prematurely; when the child possesses a hydrocephalic head; when there are locked twins; in certain cases of face presentation; and in those cases of version where by the assistance of the forceps it is impossible to deliver the after-coming head of the child.

—Prof. Fehling, of Stuttgart, whose name is most widely known in connection with the solution which he invented for the detection of sugar, died a few weeks ago at the age of 72.

# A CASE OF ENUCLEATION WITH REPLACEMENT OF THE HUMAN GLOBE BY THAT OF A RABBIT.

BY H. W. BRADFORD, M.D.

*Assistant Surgeon Massachusetts Eye and Ear Infirmary.*

REPORTED BY H. B. CHANDLER, M.D., LATE SENIOR INTERNE.

This operation, sufficiently novel to justify publication, was performed August 9th, in the presence of several medical gentlemen, the reporter assisting.

The patient was a seaman in good health, and about thirty-five years of age. In consequence of an injury received in early childhood one of his eyes had become atrophied, and, as is usual in cases of such long standing, the globe was very much atrophied. The operation for the removal of the stump was conducted in the usual manner, with the exception that a strabismus hook was passed beneath the recti muscles, and a suture inserted previous to their division from the sclerotic.

The atrophied globe having been drawn forward, a needle was entered through the conjunctiva close to the inner canthus, the nerve found, and a suture inserted as near the centre of its substance as possible. The nerve was now divided close to the sclerotic, the stump was removed, and the resulting hemorrhage, which was trivial, controlled by ice.

The next stage of the operation was the removal of the eye from the rabbit. A rabbit having been obtained whose iris nearly matched the color of the patient's eye, a circular incision was made in the conjunctiva about 5 mm. from the cornea, the conjunctiva carefully dissected backward, and the tendons of the recti and obliqui divided close to their insertion. The eye being now drawn outwards, the nerve was cut at about 8 mm. from its sclerotic entrance. The cavity of the patient's orbit being, by this time, perfectly free from blood, a little albumen from a fresh egg was poured into it, and the rabbit's eye also dipped in albumen previous to putting in place. The suture, which had previously been passed through the patient's optic nerve, was drawn forward and inserted into the optic nerve of the eye, and by means of a peculiar double slip-noose the ends of the nerves were brought into apposition; one end of the suture was cut short, and the other, which had been passed through the conjunctiva, near the inner canthus, was firmly secured by means of a piece of adhesive plaster to the nose. The object of thus securing it was to prevent its being subjected to any tension, which would have resulted in the removal of the slip-noose. The four recti muscles were next brought into position, and sutured to the sub-conjunctival tissue, and the conjunctiva attached by four sutures to the band of the same tissue which had been left around the cornea.

The lids having been closed, iodoform was dusted over them, and a pad of absorbent cotton and flannel bandage applied.

For seven days the parts were left undisturbed, but the patient was carefully watched for any fibrile disturbance. Nothing of such a nature, however, occurred, nor was there any offensive odor perceptible. On the seventh day, upon removal of the bandage and pad, nothing of an abnormal character was observed about the lids, except a small amount of mucus gluing the lashes together.

The eye itself was next carefully examined. The cornea presented a slight haziness, but this seemed to be superficial; the conjunctiva chemosed and over-lapping the cornea in all directions, except externally,

where the sclerotic coat was exposed for a space about 8 mm. long, and 6 mm. wide. This condition was found to be due to the premature sloughing of the suture through the external rectus, which having contracted, had drawn the conjunctiva with it. The movement of the eye was good in all directions, except that divergence was imperfect. The suture connecting the nerve was withdrawn, as were also those of the superior and internal recti; but the inferior being still found firmly adherent was allowed to remain. Atropine was dropped into the conjunctival sac, the eye closed, and iodoform and compress used as previously.

On the twelfth day after the operation the eye was again examined, as the patient complained of some annoyance in it, this being the first complaint he had made. It was discovered that the remaining suture attached to the inferior rectus had sloughed out, and was found under the lower lid, this, no doubt, being the cause of the slight sense of irritation experienced by the patient. The condition of the eye was as follows: cornea hazy, but somewhat less so than when previously examined; conjunctiva well united around the cornea and to the globe; exposed sclerotic on outer side had become covered to about half of its extent; recti muscles working satisfactorily, with some improvement in divergence over that manifested before. Atropine, iodoform, etc., used as previously, until the present time of writing, eighteen days after the operation. To-day the condition of the eye is as follows: conformation and tension good; cornea improving, and has cleared peripherally so as to allow the iris to be distinctly seen; chemosis of the conjunctiva has disappeared, although the membrane remains congested; exposed sclerotic on outer side of the eye practically covered by the conjunctiva; ocular movements in all directions good.

The object of the operation above described was partly experimental—an endeavor to ascertain whether a whole organ could be nourished sufficiently long to have a vascular supply established. In this respect, we believe that a reasonable degree of success has been obtained.

Vision was not expected in the transplanted organ in any case, for the optic nerve was composed principally of connective tissue, and diminished to half its normal size. The principal aim, therefore, in this case, was to obtain cosmetic effects.

The patient was desirous of obtaining an artificial eye, but his occupation being that of a seaman, the nature of his calling made it undesirable to use a glass artificial eye on account of its liability to be broken. It was therefore resolved to attempt this experiment.

The value of the operation cannot from one trial be fully estimated, and it is extremely dubious whether vision could be obtained by the union of the optic nerve. That it would prove, however, of some practical value in the case of children upon whom enucleation has been performed, is credible, for it is well known that in those cases the orbital cavity is imperfectly developed. It is true that we would not expect the globe to increase in size as if a fully-matured rabbit's eye was taken; but Dr. Bradford suggests that the substitution of a young dog's eye might obviate the difficulty, as it would, in all probability it well nourished, increase in size as it would have done in its normal position. Cosmetically, it could be used in those cases that are often met with where an artificial eye cannot be used on account of some deformity in the conjunctiva or lids.

I might mention that the albumen was used empirically, as we had found in alloplastic operations that dipping the flap in albumen previous to adjustment produced excellent effects. Whether it assists in nourishing the transplanted tissue, or on account of its adhesiveness that it is of advantage, has yet to be determined.

### THE HYPODERMIC ADMINISTRATION OF MORPHINE AS A SUBSTITUTE FOR HANGING IN THE EXECUTION OF CRIMINALS.<sup>1</sup>

BY FREDERICK HENRY GERRISH, M.D.

*Surgeon to the Maine General Hospital, Professor of Anatomy in Bowdoin College, etc.*

CAPITAL punishment is an approved method of dealing with certain classes of criminals in Maine. Within a few weeks two men have suffered this extreme penalty in the state prison; two more men and a woman are to be executed there before the year ends; and, judging from the frequency of murder of late, and the apparently growing disregard of the sanctity of human life, the number of persons whom the State will desire to exterminate annually in the future will be not less than that judicially killed in 1885. In view of this condition of affairs, it behooves the medical profession, which, more than any other class, has knowledge of the processes of living and of dying, to consider the means adopted by the legal authorities for taking lives which have been forfeited to the State, to decide whether or not these methods are humane, and to advise the law-makers concerning improvements, if any, are necessary and possible. I bring this subject to your notice because of my conviction that the present usage is antiquated and barbarous, and because a substitute for it can readily be found which is free from objectionable features.

It is not my purpose to attempt a historical account of execution by hanging. Suffice it to say that it has long been the favorite method of putting criminals to death in the English-speaking countries, and was doubtless adopted on account of its supposed superiority to others in point of humanity. That hanging is sometimes sudden, painless, and as free from hideous display as such a process well can be, is freely admitted; but that it is often slow, painful, and altogether horrible, is known to all men. Occasionally the rope breaks, and the victim falls to the ground, only to be picked up and dragged again to the scaffold, to experience once more the bitterness of death. Once in a while the long drop effects decapitation, and we have the bloodiness of the guillotine, without the neatness of its cut.

Last winter in England a condemned man was on the scaffold, the last words had been spoken, the bolt was drawn, but the drop did not fall. The convict was removed, the apparatus was tested, and again the intended victim was put in position. A second and a third time did the drop fail to act when released, and then the poor fellow, who had thrice looked death calmly in the face, fainted and was carried back to his cell. His sentence was commuted, and the people said Amen. So frequent are the bunglings and failures, that those who have the business in charge are always nervous till the affair is over. Said the assistant-warden, in response to a congratulation on the success of the recent hanging at Thomaston, "Yes, it passed off

well; but we have been very anxious about it for three weeks. The last one we had here was not so successful!" Indeed, it was not, as any one who witnessed it can testify. I have no hesitancy in pronouncing so imperfect and cruel a method of taking human life, entirely unworthy of the civilization of the nineteenth century.

In our search for a substitute, we naturally consider the methods employed by other nations, and we find that none of them possess qualities which commend them to our judgment. The guillotine, the garrote, and shooting, while presenting certain advantages, would, for obvious reasons, never find favor with Anglo-Saxons of this age, and crucifixion is not to be thought of. Electricity has been advocated; but the apparatus for an execution would be very expensive, and it is not certain that the result would be satisfactory; for many times men have received electric shocks which anybody would have supposed sufficient to cause death, and have recovered. Chloroform has been suggested; but the administration of this drug might require a considerable time, and there would always be a strong probability of struggling and delirium, with the wild shouts, and yells, and imprecations. Prussic acid might be used, but for the danger to which the anhydrous article would expose the person administering it, and the chance of convulsions resulting from a dose not immediately paralyzing to the powers of life.

The method which seems best to me is the hypodermic administration of morphine in a lethal dose. I am not aware that it has been proposed before; at all events, the plan is new to those to whom I have mentioned it, and seems worthy of serious consideration.

The details of the execution would be as follows:—

At the appointed time, the sheriff, accompanied by two deputies and the citizens prescribed by statute, enters the cell of the convict, who is lying on a couch. The sheriff administers six grains of sulphate of morphine under the skin of the felon, who, in a few moments begins to be drowsy. Soon he is overpowered with sleep, and the officer, to make assurance doubly secure, repeats the dose. Within half an hour the heart has ceased to beat, and the man is dead, having passed away without pain, convulsion, struggle, or consciousness.

The advantages of this method are its certainty, its painlessness, the freedom from the chance of horrible displays, the reduction of the dramatic element to a minimum, and its inexpensiveness.

(1) No one will dispute the certainty of the result. If anybody fears that the dose is too small, it can be repeated over and over again, so that the end may be greatly hastened. There is no possibility of the rejection of the poison.

(2) The convict is caused no suffering, for the slight sting of the hypodermic injection is unworthy to be called pain.

(3) There are no convulsions, no decapitation, none of the hideous phenomena that often attend a hanging; the man simply goes to sleep, never to awake.

(4) Many of the criminals who are condemned to death, and find that a change of punishment is impossible, make the most of their situation, and try to glorify themselves in the eyes of their friends by "dying game" on the gallows, and carrying themselves jauntily on the threshold of eternity. The exclusion of the public from executions has greatly diminished the opportunities for spectacular display; but the quiet and

<sup>1</sup> Read before the Maine Medical Association, June 9, 1885.

seclusion of the cell in which the fatal dose of morphine is taken reduce these chances to their very lowest terms. A villain on the scaffold, in full possession of his faculties, anticipating instant extinction, may appear heroic; the same man submitting to the trivial puncture of a hypodermic needle, and presently becoming too stupid to keep his eyes open, is far less likely to consider himself, or be thought by others, a hero.

(5) The cost of erecting the gallows is considerable; that of a hypodermic syringe and morphine insignificant. It may be a small matter to discuss; but, after the State has been at the expense which a murder-trial usually costs, generally paying the fees of the defendant's counsel, as well as those of the prosecution, it is not improper to desire that the last act of the tragedy may be as inexpensive as possible.

Various objections are made to the proposed change, and these will be considered and answered seriatim.

(a) It is said that the sheriff cannot inject the morphine skillfully. If one but recalls the ease with which he himself learned how to use the hypodermic syringe, and the number of people in his acquaintance who acquired all too readily the necessary skill for administering doses to themselves, he will see the weakness of this objection.

(b) The slowness of the dying is thought to be undesirable. But in this, as in other affairs, the thing is quickly enough done, when it is well enough done. At the worst, the time will not be very long, and every minute will show that the man is sinking into a rapidly deepening sleep.

(c) It is suggested that convicts might be opium-eaters, or might train themselves so that their nervous systems would be incapable of receiving a fatal impression from morphine. To say nothing of the supposition that any person might not be poisoned to death by morphine, it is to be observed that the law requires that the time for execution shall be not less than twelve months from the day on which the sentence is passed, in which time, as the state does not supply its prisoners with drugs to be taken for merely intoxicant effects, the opium-habit would be cured, or its slave be dead,—an arrangement to which nobody would object.

(d) It is objected that the publicity of an execution is diminished by the projected method, and the chance to impress the people is lost. The present law allows but few to attend an execution, evidently with the design of avoiding publicity, for the effect on the community of an old-fashioned hanging was believed to be extremely harmful. A sufficient impression is made on the populace by the announcement of the fulfillment of the law; the chief purpose of which is the permanent removal of a worse than worthless member of society.

(e) Some have said that they do not object to having felons endure some physical pain. Obviously the people do not entertain such views; for they have abolished torture and those forms of execution which are always painful, like crucifixion; and I believe they have retained hanging so long only because no plainly better plan has been advocated. The effort always is to make the death by hanging as sudden and painless as possible; and, when it is not so, we blame the executioner.

(f) It is objected that criminals dread death by hanging more than they would that by morphine, and

thus are deterred from committing deeds which they would venture upon, if an easy poison were substituted for the rope. This seems to me in the highest degree improbable; but the discussion of the point would inevitably lead to the re-opening of the question of the value of capital punishment, a subject which it would be improper to introduce here. It is well, however, to remember that the deprivation of opportunity for a dramatic exhibition would be so serious a matter to a convict that it would be almost like adding a sting to death.

In the distant future there will probably be judicial processes by which undesired lives other than those of criminals may be brought to an end. How often we have reason to wish for such a law, for the sake of those whose usefulness and happiness are blighted by the existence of some hopelessly demented dependent, who demands constant attendance; what a blessing it would be to the poor wretch smitten with an inevitably fatal disease, racked with unceasing pain, a nuisance to himself and a grievous burden to those whom he loves. If such a statute were in existence now, and it were given to us to decide what method should be pursued for bringing the unwished for existence to a close, would not every one of us write on his note morphine? And would we not choose this poison because accident has shown us many times that death by it is like another sleep, is painless, quiet, and not disfiguring? These are the very characteristics of the typical execution, qualities which hanging often has not, but which, I predict, the judicial killing of the future will always exhibit.

## RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M.D.

THE RELATIONS OF THE LARYNX AND TRACHEA TO THE VERTEBRAL COLUMN IN THE FÆTUS AND CHILD.<sup>1</sup>

MR. J. SYMINGTON has written an excellent paper on the position of the epiglottis, the lower border of the cricoid and the bifurcation of the trachea in fetuses and young children. He has had recourse to frozen sections and has carefully noticed the position of the head in each case, as this seems to exercise an influence on the relation of the parts. He has examined in this way five fetuses, seven children up to two years and two months, and three children of five, six and thirteen years, respectively. A greater number is, of course, desirable, but these observations form a nucleus. To show the effect of position of the head, Mr. Symington cites the freezing of the bodies of two children about two years old and of just the same length, one with the neck strongly flexed and the other with it well extended. In the former, the lower border of the cricoid was at the level of the upper border of the sixth cervical vertebra, in the latter, it was a vertebra higher. In the former, the bifurcation was opposite the lower border of the fourth dorsal, in the latter, opposite the upper border of the third. The series shows a gradual descent of the lower border of the cricoid. In the youngest fetus, one of about four months, it was opposite the upper border of the fourth cervical. In a child of three and a half months, it was at the lower border of the fourth, and at one of six months, at the upper border of the fifth. It does not

<sup>1</sup> *Journal of Anat. and Phys.*, Vol. XXX., part 3, Apr. 1, 1896.

go below this point with the head erect till we reach the child of five years, when we find it at the upper border of the sixth. In the child of six it is a little higher again, but unfortunately, there is a great gap in the observations after we pass two years. In the girl of thirteen, the lower border of the cricoid was at the upper edge of the seventh vertebra, but the head was flexed. Mr. Symington thinks that, otherwise, it would have been opposite the middle of the sixth. The adult position is at the lower border of the sixth. Does this change depend on the more rapid growth of the larynx or simply on its downward displacement? Apparently, on the latter. The position of the tip of the epiglottis is not easily placed with accuracy and is subject to too many variations to be of great value, but it is clear that the whole larynx moves downward, and the author suggests that it is due to the development of the face.

The position of the bifurcation of the trachea, which, in the adult is at the lower border of the fourth dorsal, (we believe it is often lower) changes from opposite the second dorsal, where we find it in fetuses of six and seven months. At two years it has nearly reached its resting place. We find that the author has stated in a previous paper that in a child of two years, with the head fully extended, it was at the lower border of the first dorsal. His later investigations do not appear to confirm this theory, and we cannot think that it is usually so high. It is very possible that in early childhood, and still more in infancy, the position of the neck may influence that of the bifurcation, but we doubt very much if it does so in adult life, when the spine and ribs have become much more rigid.

#### THE MEANING OF THE SEMILUNAR FOLD OF DOUGLASS.

This is the name applied to the free edge of the fascia of the transversalis and internal oblique on the posterior border of the rectus abdominis at the line about midway between the umbilicus and pubes below which the aponeuroses of all the abdominal muscles pass in front of the rectus. Above this line, the aponeurosis of the internal oblique splits into two layers, the front one joining the external oblique to pass before the rectus, and the other joining the transversalis to pass behind it. The lower edge of the latter is semilunar and usually a distinct feature. Sometimes, however, it is not very evident and it is said not to be present in the fetus. The above description is the one usually given in English works on anatomy. We believe that it is frequently taught that this arrangement allows the recti to spread apart in pregnancy or in great distention of the abdomen from other causes. This explanation, though at first sight plausible, is not very satisfactory, as the separation of these muscles is often observed decidedly above the fold in question.

In 1836, Retzius gave a very different account of this structure. According to him the line marking the fold is a thickening made by the fusion of the lower border of the posterior layer of the sheath of the rectus, with the *fascia transversalis*, which, lying before the peritoneum, joins the pelvic fascia below. Thus a preperitoneal space is formed to receive the bladder when it rises above the pubes. To this it has been objected that the bladder in the adult never rises so high except perhaps in extraordinary cases of distention, and that precisely at the time when it is an abdominal organ, the fold does not exist. Still another view, supported by Henle and Luschka, is that

it is to be considered as a tendinous band arching over the epigastric vessels as they pass to the rectus. To this is replied that though such arches are common, they bear some relation to the size of the structures passing under them, and that here the arch is absurdly large.

We are indebted for most of these historical remarks to a paper by Professor B. Solger<sup>2</sup> of Halle, who gives a new, and on the whole, a satisfactory theory. He finds the explanation in mechanical arrangements.

Thus, in deep inspiration, when the lower ribs spread outwards, their overexpansion is prevented by the firm aponeurosis coming from that part of the two inner muscles attached to them which runs to the linea alba above the fold. Its action, however, is not only that of a check ligament. It plays an important part in expulsive efforts, when, the glottis being closed, the expiratory muscles (and we must add the diaphragm) contract at once. The lower portion of the abdominal wall bulges forward while the upper is drawn in by the action of those portions of the internal oblique and transversalis that arise largely from bone and cartilage in contradistinction to the lower portions that arise from Poupart's ligament. The upper portions, in short, are the ones that do the work and consequently have the firmer aponeurosis.

#### THE VENOUS SYSTEM OF THE BLADDER AND ITS SURROUNDINGS.

This paper<sup>3</sup> contains the results of very praiseworthy anatomical work. As we have repeatedly remarked, the venous system has received but a small part of the attention it deserves. The difficulties are so great as to deter any but the most patient investigator. Mr. Fenwick points out that the advice to choose old subjects for the purpose is very bad, as the veins and the valves are likely to be changed from their normal condition. He says that young subjects should be chosen, and he has even pursued his studies on fetuses. Moreover, he does not use a solid injection, as this does not permit the demonstration of the valves, a point on which he justly lays great stress. It is worth while to quote a paragraph in which he describes his method.

"My earlier dissections were all made after the venous plexuses had been inflated, the knife cleaning the tense veins with certainty and ease. Colored fluids had been thrown in, in a direction, which, in the living subject would be opposed to the normal venous current. The valves were easily seen through the thin-walled veins punched by the force of the fluid. Their situation was then marked on a plan previously taken of the dissection. Much labor was thus expended, each vesico-prostatic plexus and its connection often demanding more than a week's continuous work. I soon found it to be a quicker method to dissect out a small tract of a vein at a time, to clamp each end of the exposed piece, to make a diagram of it, and to inject it with fluid colored with Berlin blue. If the injection was suddenly arrested, and a corresponding swelling at the right of the obstruction was observed, the vein was incised over the obstruction and generally a valve exposed. It was then depicted."

Mr. Fenwick very aptly compares the venous system of the pelvis to a room having but one exit and many entrances, each of the latter being guarded by a door

<sup>2</sup> Morphologisches Jahrbuch, Band XI, Heft I, 1885.

<sup>3</sup> By E. H. Fenwick, F.R.C.S., Journal of Anat. and Phys., Vol. XIX, Part 2, April, 1885.

opening inwards. "Hence," he says, "the abdomino-pelvic venous blood-pressure is entirely shut off from that of the lower extremities and genitals. The accuracy of closure and constancy of position of these entrance-valves is most striking."

He finds three sets of valves in the plexus of Santorini. One just behind the pubes, another near the end to guard against reflux from the internal iliac vein, and a third, of less importance, between the two. Mr. Fenwick describes two muscular bundles from the front and lower surface of the bladder that pass over the upper and anterior surfaces of the prostate and are inserted in part into the pubes and in part blend with the anterior fibres of the levator ani. When the bladder contracts, these muscles compress the plexuses and prevent regurgitation into the valveless veins of the anterior inferior portion of the bladder. The subperitoneal veins of almost the whole of the bladder tend towards the outer and posterior parts of the plexus so as not to interfere with the current from the genitals. They are well protected with valves at their entrances.

#### THE CORPUS CALLOSUM OF THE HUMAN BRAIN.

It is, we believe, considered as perfectly established that the corpus callosum is a mass of white fibres connecting corresponding parts of the cerebral hemispheres; in other words, that it is a commissure. This view has not always been universally held, but of late no one has disputed it and it has been tacitly accepted as one of the best established facts in cerebral anatomy. Professor J. D. Hamilton's<sup>1</sup> paper, giving the results of many years' work, in which he maintains a very different view, is, therefore, of great importance. We will not attempt a detailed analysis, but give merely a rough sketch of his scheme. The cardinal point is that the corpus callosum is not a commissure at all, that the fibres do not connect corresponding groups of cells, but that it is a decussation in which the fibres from the gray matter of one hemisphere cross those from the other and run into the inner and outer capsules of the opposite side.

Thus the great mass of white fibres in the hemisphere consists of fibres ascending from the deeper parts of crossed callosal fibres, and of groups of association fibres connecting different parts of the cortex of the same side. Professor Hamilton does not believe that there are any commissural fibres at all in the corpus callosum, but admits that this cannot be proved. The crossed callosal fibres pass, as we have said, into the inner and outer capsules, but it is apparently not easy to trace them much further. The greater number naturally go to the larger inner capsule.

The author thinks that most of these can be traced into the optic thalamus. Some few go to the caudate nucleus, but he is unable to say whether any end in the lenticular nucleus. The distribution of the fibres that enter the outer capsule is more complicated, and we will mention only the set that Professor Hamilton believes can be traced into the optic tract, which is also, we believe, an entirely new view.

The paper before us treats only of the adult human brain, but it contains a slight reference to an article by the same author on the "Embryonic Corpus Callosum," which appears in *Brain* for July, 1885, which we have not yet seen. Professor Hamilton claims that the arrangement of the callosal fibres is particu-

larly well shown in the brain of the human fetus at four months, and that in the brain of the embryos of mammals it can be seen with the naked eye.

Should these observations be confirmed, as we strongly believe they will be, Professor Hamilton will have accomplished a great deal in cerebral anatomy. We refer those who are curious as to the methods employed to the present paper in the *Journal of Anatomy and Physiology*, and especially to one by the same author in *Brain* for July, 1883.

#### REPORT OF PROGRESS IN GYNÆCOLOGY

BY F. H. DAVENPORT, M.D.

#### ELECTRICITY IN THE TREATMENT OF UTERINE FIBROIDS.

DR. J. T. EVERETT,<sup>1</sup> who in 1878 published the account of nine cases of uterine fibroids in which he had used at some stage of the case, the electrolytic current, gives in this article notes of seventeen additional cases. From their careful study he says there are three lessons to be learned: (1) That for intra-uterine fibroids the faradic current is amply sufficient to effect a cure, and for obvious reasons is the one to be selected, as it causes the uterine muscles to contract, choking off the afflux of blood, thus destroying the vitality of the tumor, separating it from its environments, and assisting in its extrusion. (2) For submucous or intra-mural fibroids, the continuous current from twelve to eighteen cells will be found to act powerfully as a resolvent, causing the tumor to shrink and solidify, and separate from its capsule. (3) That where the stronger electrolytic current of from twenty to seventy cells is used, there is intense pain unless anaesthesia is employed. There is systemic shock, with resultant destruction of healthy and diseased tissue, and supuration. In this connection it is well to recollect that the nearer the points of entrance and exit of the current, the more rapid the result.

#### REMOVAL OF OVARIAN TUMORS WITH RETENTION OF THE OVARY.

Schroeder<sup>2</sup> gives the history of six cases where, after removing the larger tumor and ovary of one side, he found a smaller one connected with the ovary of the other side, but was able to dissect it out and leave part of the organ. The patients were young, and in several of the cases did not wish to give up the possibility of conception. One, a well-marked bleeder, died of slow hemorrhage. The others recovered, and have menstruated regularly, but have not conceived. The author considers that the retention of the menstrual function and the theoretical possibility of conception is so important to many young women that this procedure is of value in such cases. In older women, and with those who have had several children, it would be a useless refinement.

In the discussion, Dr. Martin said that the possibility of the development of another tumor from what was left should not be lost sight of, especially as a second operation had its own dangers. In the first place, there are usually adhesions, which make the operation more difficult, and in the second place, the presence of the scar of the former operation made the union less sure. His practice was to cut the scar out entirely, and the result was good.

## THE TREATMENT OF INTRA-UTERINE DISEASE.

Three papers on this subject<sup>3</sup> were read before the Obstetric Section of the British Medical Association, at the Fifty-Second Annual Meeting.

Dr. Loube Athill opened the discussion by a paper in which, after referring to the prejudice which formerly existed against treating the uterine mucous membrane as similar surfaces in other situations are treated, a prejudice which is fast disappearing, the author takes up the consideration of the best method of making such applications as may be necessary. He briefly sums up the conditions which demand such treatment, thus: "all affections of local origin giving rise to profuse menstruation, metrorrhagia, or uterine catarrh, or in which hyperæsthesia of the nerves distributed over the inner surface of the uterus exist." Polypi and other tumors he would exclude, but certain forms of recurrent growths, and of malignant diseases, are to be included. He specifies "local origin" in order to guard against conditions dependent upon affections of the tubes and ovaries being treated in this manner.

The agents he would employ are borax, iodine, carbolic acid, iodized phenol, nitric acid, iodoform, and solid nitrate of silver. Of these remedies, the author finds he uses carbolic acid in nearly seventy per cent of cases requiring intra-uterine medication, iodized phenol in about fifteen per cent, and nitric acid in three per cent. Borax in the form of a saturated solution in glycerine he uses very occasionally in exceedingly mild forms of catarrh, which have nearly yielded to harsher remedies. Iodine, either in form of tincture or liniment, he considers very inert, as probably very little is absorbed, and its action is mainly caustic. Carbolic acid is the most useful agent, both for curing catarrhs and relieving pain. It should be applied every three or four days, and its use continued some weeks. Iodized phenol, which is iodine dissolved in carbolic acid, one part to three or four, is of great value in certain cases, especially of hæmorrhage. Nitric acid is the most active of the agents. It does not cause much pain, but the cervical canal should always be protected by a tube of vulcanite or platinum. Iodoform is used in the form of slender crayons in some cases of dysmenorrhœa, and of fetid discharge from the uterus. The solid nitrate of silver as recommended by Sir James Simpson for menorrhagia, depending on subinvolution of the uterus, does not act very satisfactorily, and the author rarely uses it.

All of the agents except iodoform and solid nitrate of silver are used by winding a bit of cotton on a flexible probe, and passing it into the cavity of the uterus. By using dry cotton first, and so removing the mucus, the application will reach the uterine mucous membrane more thoroughly.

There are four conditions where it is necessary to adopt other means: (1) When the mucous membrane is so vascular that the introduction of the probes is followed by hæmorrhage. (2) When the cavity is of large size. (3) When hæmorrhage occurs as the result of vascular growths. (4) When epithelioma affects the cavity of the uterus. For all these conditions the author has been in the habit of dilating, curetting, and applying nitric acid with very good results except in cases of epithelioma. In four cases, the details of which he gives in full, where there was a vascular growth inside the uterus, and where nitric acid failed to control

the hæmorrhage, he was induced to try injections of iodized phenol, diluted with an equal part of alcohol, a method which was successful in restraining the hæmorrhage, and prolonging the patients' lives.

Dr. Thomas More Madden, in his paper on the same subject, after a short historical introduction, speaks of the methods of dilating the uterine canal, as by graduated series of dilators, where the tissues are lax, or by tents, especially laminaria, when there is more rigidity. Oftentimes to get the best effect of the agent applied, even when there is no abnormal growth, a moderate curetting beforehand is of advantage. The majority of cases calling for intra-uterine medication, are, according to Dr. Madden, those of what we should call areolar hyperplasia and subinvolution of the uterus. For this treatment he recommends fuming nitric acid applied with the necessary precautions after thorough dilatation of the canal. Milder applications of carbolic acid, iodoform, and tincture of iodine are recommended later.

For the treatment of tumors within the cavity of the uterus, if submucous or pedunculated, he advises enucleation or écrasement. Within the past few years he has removed forty-two such tumors with thirty-nine recoveries and three deaths. He ends with urging the importance of general as well as local treatment in these cases.

Dr. John W. Byers emphasizes the importance of the rôle which general endometritis plays in the production of the various changes in the mucous membrane and the resulting symptoms which call for intra-uterine medication. Of the four methods, by injections, by the introduction of remedies in the solid form, by ointments, and by swabbing or painting the remedies over the interior of the uterus, he prefers the last. His testimony as to the relative value of the different solutions recommended, and as to the use of the curette, agrees with that expressed in the other papers.

## A NEW EXPLANATION OF THE PROCESS OF MENSTRUATION.

Lowenthal,<sup>4</sup> in this exhaustive article, gives a new theory of menstruation which shows marked originality and research. It would be impossible in the short limits of this report, to give an abstract of the elaborate train of reasoning by which he arrives at the results. They are summed up briefly at the end, and we would refer those interested in the subject to the article itself for the minutest details. He makes the following propositions:

I. The periodical flow of blood from the female genitals is not a consequence of the rupture of a follicle, (which usually occurs at the same time), but of the degeneration of the uterine mucous membrane which has become hypertrophied before such rupture, and independently of it.

II. This growth, the menstrual decidua, is caused by the imbedding in the unimpregnated condition of the last ovum furnished by the ovaries.

III. If this imbedded ovum is impregnated, the menstrual decidua becomes that of pregnancy, but if the ovum remains unimpregnated, it degenerates as a consequence of the death of said ovum.

IV. Taking each menstruation for itself, the rupture of the follicle and the flow of blood stand in no other causal relation to each other than that possibly the causes and conditions which are operative at the

occurrence of the hemorrhage may, at the same time, have an effect in bringing about the rupture of a ripened follicle.

V. The coincidence of the rupture of a follicle and the flow of blood is, therefore, no necessary one. Each can occur separately; a follicle can rupture without there being any menstrual decidua present, and this secondary consequence of the ovum which has previously made its appearance, namely, the menstrual flow, can occur without a new follicle rupturing at the same time.

VI. The periodicity of menstruation is determined by the extra-follicular length of life of the imbedded and unimpregnated ovum; the variations from the general or individual periodicity depend upon the shortening or absence of such capacity for life, either idiopathic or the result of intercurrent influences.

VII. The ovum which has been expelled, usually at the last menstruation, and is present ordinarily in the uterus (in abnormal cases elsewhere), is the one which is impregnated.

From these the following practical conclusions can be drawn:

VIII. Since the menstrual flow is neither a physiological function, nor the necessary accompaniment of such a function, but the direct consequence strengthened by innumerable repetitions of a process which is the result of our social conditions, namely, the unimpregnation and death of the human ovum, therefore it has all the properties and results of other hemorrhages which are always pathological.

IX. It increases and diminishes under like conditions with them.

X. The flow of blood which is the necessary accompaniment of the menstrual decidua, is only to be regarded as harmless when it occurs per diapedesin. When per rhexin, it is under all circumstances unnecessary, and becomes injurious when it is felt and responded to by the entire organism as a loss.

XI. The amount of the injury corresponds to the proportion between the amount of blood lost, and the quantity (plus the quality) of blood which the body contains at the time.

XII. Under these circumstances the indication is for the greatest possible reduction in the amount of the menstrual flow, as of any other loss of blood.

XIII. The means to be recommended are first and foremost rest in bed, and hot water injections.

XIV. On the contrary, the voluntary cessation of the menses (idiopathic amenorrhoea), is under no circumstances to be regarded and treated as a disease; it is only a sign that a function (ovulation) which is not necessary to the life of the individual, from some cause or other (youth, age, pregnancy, lactation, debility), was not properly performed at the proper time, that is about four weeks previously.

XV. Supported by this theory, and the observation of Lawson Tait as to the importance of the tubes for menstruation, it would be desirable to attempt to substitute for castration, salpingotomy (partial resection of both tubes after previous ligation), in those cases where uterine dysmenorrhoea, menorrhagia, fibroids, and such uterine affections call for the anticipation of the menopause.

XVI. Should it appear impossible after beginning the operation for castration in the above mentioned conditions, to completely remove the ovaries, salpingotomy would be directly indicated.

# ABDOMINAL SURGERY.

The *British Medical Journal* for January 31st, 1885, has several articles on this subject. Thomas Keith gives notes of thirteen cases of supravaginal hysterectomy, in addition to the twenty-five previously reported. One of the last thirteen died, giving a mortality of three in the thirty-eight cases. He has also removed the ovaries to check the growth of fibroids, twelve times with no deaths. The death in the last series of hysterectomies was from asthenia in a patient whose case was almost hopeless from the beginning.

He has no routine method of treating the stump, but says each case must be a law unto itself. He questions the justifiability of operating in cases of fibroids, unless the mortality can be kept down as low as, or lower than his eight per cent, for the mortality of cases of ordinary uterine fibroid if left alone, is nothing approaching that. An imperfect list of hysterectomies collected by Dr. Bigelow of Washington, gives three hundred and fifty-nine operations done by sixteen of the most successful operators, of which there were two hundred and twenty-seven recoveries and one hundred and thirty-two deaths.

Dr. Keith again refers to the use of carbolic spray in abdominal operations. He not only considers it useless but harmful. In ovariectomy before he began spray, his results were one death in twenty-six; under the use of spray one in seventeen, and since he abandoned it, about the same as before he used it. He has given it up in hysterectomies. Increased success has come from two causes: first, development of the technical methods of operating, and second, thorough cleanliness. "It was," he says, "the willing and tender, though unclean hand of the surgeon, that carried most of the poison into the wound. It is to this that Lister has put a stop."

Dr. T. Oliver reports a case of parovarian dropsy, cured by a single tapping, and urges this method of treatment when the diagnosis is clearly made out, in preference to abdominal section, and removal.

Dr. T. Savage gives the results of the work in abdominal surgery done by him in 1884, consisting of one hundred and four operations. There were nine deaths, three from septicaemia, four from asthenia, one from tetanus, and one from granular kidneys. Dr. Savage lays stress upon the importance of operating early, and feels confident he could have saved several of his cases which were brought to him virtually "in extremis." He very strongly advocates drainage with long glass tubes, which should be carefully watched. He believed that pyosalpinx is most frequently due to gonorrhoea, and the best treatment is by abdominal section. In two cases after removal of the appendages a large hematocoele formed, giving rise to serious symptoms. In the third week he opened the abdomen a second time, let out the blood and pus, and inserted a drainage tube. He is of the opinion that acute peritonitis is a symptom of some organic change, and not a disease itself, and thinks that operative measures can do much for it.

Lawson Tait recently communicated to the Midland Medical Society a record of one thousand operations of abdominal section which he had performed. Of these there were: exploratory incisions, ninety-four, parovarian cysts, sixty-five, cysts of one ovary, two hundred and thirty-nine, cysts of both ovaries, one hundred and one, appendages for myoma, ninety-nine, ditto for in-

flammatory disease, two hundred and one, hysterectomy, fifty-four, and the rest for various other less frequent causes. Total number of deaths ninety-three, or nine and three-tenths per cent. This mortality he considers high, but it includes his early work. In a second series of cases he feels certain that his mortality would be much lower, not only through greater experience, but because he has abandoned the clamp in ovariectomy, and the ligature in hysterectomy. His mortality in the latter operation, thirty-five per cent, he attributes chiefly to hemorrhage, which resulted from trying intra-peritoneal methods. He groups all his cases of pyo-, hydro-, and hamato-salpinx, and chronic ovaritis, under "Removal of Appendages for Inflammatory Disease," as "the clinical symptoms are similar, and a hard and fast nomenclature cannot be established." In thirteen cases of this class there was little or no relief for a time varying from six months to two years, and in all of them an accident occurred in the effusion of a large quantity of blood into the circum-uterine tissues, generally within a week after the operation. This was accompanied by increase of pulse and temperature, pain, and a condition of invalidism lasting a varying time. In one case Mr. Tait reopened the abdomen after four months, and cleared out a small quantity of pus with complete relief.

#### CIRCULATION OF THE UTERUS.

Dr. John Williams<sup>2</sup> read a paper on this subject before the Obstetrical Society of London. After referring to the importance of carefully studying the circulation in the uterus, he describes the course of the ovarian and uterine arteries. All the primary branches enter the uterus on the side, and run a superficial course, being separated from the peritoneum by only a thin layer of muscular fibres. The layer of connective tissue in which they run is distinct especially in fetal and infant life. The smaller branches run towards the mucous surface in a perpendicular direction, anastomosing freely, and ending in capillary loops. The veins are arranged in a similar manner, and convey the blood into the venous plexuses which are situated in the layer of connective tissue already mentioned, and communicate freely with the venous trunks outside. The return of blood is said to take place principally through the ovarian veins, but both these veins can be tied without appearing to materially affect the return of blood from the uterus,—indeed the whole of the pelvic venous system can be injected through any one of its larger trunks. The following conclusions are drawn: (1) The layer of connective tissue in which the arterial circles run, and in which the venous plexus lies, is the sub-mucous tissue of the uterus. (2) The whole thickness of the wall between this layer of connective tissue and the uterine cavity is the mucosa uteri, and the thin layer of tissue shed at the menstrual period, and reproduced, (the menstrual decidua), is only a very small portion of the uterine mucous membrane. (3) The vascular arrangements are such that the circulation in the uterus can hardly be disturbed by mechanical causes. The distribution of the blood-vessels is such that a ligature might be placed around the uterus at any point without affecting the circulation above or below. Only compression of both broad ligaments could materially interfere with the flow of blood into or out of the uterus, and this occurs only when the uterus forms a hernia in the vaginal canal,

or in Douglas's pouch in the condition usually (but inadequately) called retroflexion or retroversion, and in procidentia. He considers the posterior displacements true hernias, the constriction at the neck of the sac being formed by the sacro-uterine ligaments. In procidentia stretching of the vessels may produce considerable narrowing of their calibre. These two conditions, hernia of the uterus, and procidentia appear to be the only displacements which can give rise to congestion of the organs.

He described the following experiment to test the influence of flexions in causing congestion. Having stitched the fundus as closely as possible to the cervix, to cause the acutest flexion, he injected a colored fluid into one of the broad ligaments. Immediately the veins of the other side became distended with the injection. On making a section the whole of the veins in the uterus were found injected. This proved that the arrangement of the vessels had already shown, that the acutest flexion did not interfere with the flow of blood from the uterus.

#### BOSTON CITY HOSPITAL.

CLINICAL CASES OCCURRING IN THE SERVICE OF DR. A. L. MASON, AND REPORTED BY W. L. MUNRO, M.D., HOUSE PHYSICIAN.

#### 1. INTENTIONAL PUNCTURE OF THE PERICARDIUM THROUGH THE LOWER LOBE OF A LUNG SOLIDIFIED BY PNEUMONIA.

JOHN D. B., thirty-three years, waiter, entered Boston City Hospital April 9th, after a debauch of three weeks' duration.

No specific history. Occasional prolonged drinking spells, temperate between whiles. No previous illness; cough for some time past, but general health has remained good.

Several days before entrance, began to feel sick and became very short of breath. Can recollect no chill, stitch-pain, etc.

Expectoration rusty. No cardiac or renal symptoms with exception of dyspnea.

Temperature 100.8°; pulse 130; respirations 45. On entrance patient well developed but somewhat emaciated, respirations short and rapid. Heart apparently negative, apex beat being in normal situation. Veins of neck distended. Signs of consolidation over whole left lung, being most marked about midway of scapula along inner margin. Urine contained a slight trace of albumen and chlorides were diminished.

Was put upon stimulants and given poultice to whole left chest. During next two days, April 10 and 11, temperature was subnormal much of time and patient lay in a partially collapsed condition.

April 12. Respiration being greatly diminished and distant over lower left back and axilla. It seemed possible that signs in left chest were due to an effusion, though heart was not displaced. Aspirated at three points in sixth and seventh interspaces about mammillary line. On first puncture a little thin purulent fluid was obtained; on the second a few drops of blood, while on the third several ounces of semi-opaque, milky fluid were obtained. In all about one pint was withdrawn. Patient experienced a slight feeling of relief after the aspiration, though breathing was not less difficult than before and cyanosis equally marked.

The next morning dyspnea and cyanosis were extreme. A moderate number of high-pitched tinkling

<sup>2</sup> Medical Times and Gazette, April 13, 1887.

râles were heard over left chest. Treatment was taken well until 1.40, when patient died very suddenly.

Autopsy showed reddish-gray hepatization of upper left lobe, fibroid metamorphosis of the lower lobe, most of the lung substance being replaced by bands of dense connective tissue in the meshes of which was the remnant of the lung substance in the stage of red hepatization. Pleural cavity entirely obliterated, the pleural surfaces being adherent by old and firm adhesion.

Pericardial sac contained a small amount of milky fluid with numerous shreds of fibrin, while both visceral and parietal pericardial surfaces were covered by a long, shaggy coat of fibrin with many bands of the same stretching across the cavity. On removing this membrane from a portion of the walls two small openings in the parietal pericardium were seen, and on introducing a blunt probe through points of aspiration on the outside, it was found to pass readily through these openings into the pericardial sac.

It will be seen that the point of puncture was one of the points usually selected for paracentesis of the thorax. Owing to the fibroid contraction the lung substance at this point was reduced to about one-half inch in thickness. The left lung being completely solidified any change in the area of cardiac flatness could only be detected at the right border, and here the pericardium was overlapped by the edge of the right lung, in a condition of vicarious emphysema. The pleural cavity being obliterated and the contents of the left chest converted into a solid mass, the needle passed readily through the contracted lung substance and entered the pericardium beyond.

## II. DISSECTING ANEURISM OF AORTA WITH RUPTURE THROUGH LUNG INTO PLEURAL CAVITY.

Gertrude T., forty-eight years, colored, entered City Hospital February 4, 1885.

Quite well until a year ago when she began to have cough with considerable purulent expectoration, dyspnea, loss of flesh, etc. Had a severe attack of "asthma" shortly after. Four months ago began to suffer from dyspnea, amounting at times to orthopnea, palpitation, oedema of legs, abdomen, etc.

On entrance suffering from orthopnea, considerably cyanosed, feet and legs swollen. Cardiac area was considerably enlarged, apex beat being in fifth intercostal space, mammillary line. Double murmur at bases, systolic being transmitted upward and to right, diastolic downward to epigastrium. Systolic murmur at apex, transmitted around axilla. Signs of phthisis over both chests, most marked on left. Pulse in right radial was lacking, but no abnormal area of dullness, no pulsation, thrill, bruit, or other evidence of aneurism could be anywhere detected.

Was given digitalis and tonics. Gained slowly until the second week in March, when she began to cough very severely and suffered much from dyspnea, and severe pain in back.

At 5.30 A. M., March 20th, the patient had a severe attack of hæmoptysis, raising in all about a pint and a half of blood. Was much prostrated after it, breathing with extreme difficulty, troubled by an incessant abortive cough with inability to expectorate. Hæmoptysis continued to a slight degree, patient becoming greatly cyanosed. Lingered until 6.15 A. M., March 22d, when she died, about forty-eight hours from beginning of hæmorrhage.

On removing the sternum nothing but clotted blood could be seen upon the L., the clots overlapping the anterior mediastinum and filling the pleural cavity to the amount of a litre. In the visceral pleura was a large rent, extending into the lung, very little of the substance of which was left intact, it being badly torn and filled with clotted blood. Opening into this lung was a cul-de-sac caused by the expansion at this point of a long cylindrical sac extending along the aorta most of the way from its origin to the coeliac axis and formed by a separation of the outer and inner coats of the aorta. This cylindrical sac communicated with the aorta through a narrow opening  $1\frac{1}{2}$  inches in length and having perfectly smooth thick edges. On removing and laying open the aorta with its appendages, an appearance as of a double aorta was presented, the walls of the aneurismal sac running back to back with the true vessel, and studded with depressions, which corresponded very well with the origins of the intercostal arteries. On looking at the heart itself, the aortic orifice was found much contracted, admitting only one finger, and the valves much thickened.

The case, therefore, was one of dissecting aneurism between the outer and inner aortic coats with sacular dilatations at two points. One of these sacs ruptured into the left lung, almost entirely destroying it, and discharging it so that it, in its turn, ruptured into the pleural cavity, which became filled with clotted blood.

## III. EXTREME SUSCEPTIBILITY TO OPIUM IN A PATIENT WITH PNEUMONIA.

C. G. F., forty-three years, hack-driver, admitted to Hospital April 24th, suffering from pneumonia affecting the lower right lobe. Was put upon stimulants and Dover's powder in 5-grain doses, the last to be given only when the cough was troublesome.

Two or three dejections during the night, one of which contained about  $\frac{5}{8}$  of fresh clotted blood. Had several large bunches of hæmorrhoids, one or two of which were inflamed.

At about 8 A. M., cough being severe, patient was given pulv. Doveri gr.v. On morning visit, patient complained of intense pain from piles. These were emptied, replaced, and a  $\frac{1}{4}$  gr. suppository of morphia inserted. This was at 11.30 A. M.

At about 1.30, patient became profoundly narcotized, pupils pin-hole, respiration stertorous and somewhat irregular, surface cold, clammy, and covered with perspiration, great pallor, and some cyanosis. Aroused with difficulty and immediately relapsed into unconsciousness. Pulse was very small and condition in all respects critical. Temperature full to  $101^{\circ}$  during period of narcotization. Was given atropia and brandy subcu., and a strong infusion of coffee by the mouth. At 8 P. M., in spite of stimulants and antidotes, the case seemed desperate. At about 12.30 A. M., patient began to regain consciousness, complained of pain in right side and of great thirst and dryness of throat. Recovered gradually during the night.

It will be seen that the patient had received Dover's Powder, gr. v. at 8 A. M.; Suppository Morphia, gr.  $\frac{1}{4}$  at 11.30 A. M., or Opium gr.  $\frac{1}{4}$  by mouth and Morphine gr.  $\frac{1}{4}$  by rectum, and that narcotization had followed. It was afterward found possible to relieve patient of pain and secure sleep at any time by the administration of from  $\frac{1}{2}$  to  $\frac{3}{4}$  of a grain of morphine in solution. Considering the case as a whole it would seem to have been, without doubt, an instance of very

unusual susceptibility to the influence of opium, or of natural susceptibility greatly increased by the altered conditions in the lungs.

### Reports of Societies.

#### SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT R. DIXON, M. D., SECRETARY.

April 15, 1885. DR. JAMES R. CHADWICK in the chair.

DR. ROBERT B. DIXON read a paper entitled

#### IS CRANIOTOMY UPON THE LIVING FŒTUS EVER JUSTIFIABLE?

DR. J. P. REYNOLDS said that he did not find himself inclined to dissent materially from the reader's opinions. It is one thing to give theoretical approval to abdominal section, and quite another to make it a feasible alternative in the presence of obstetric emergency. In the interest of charity, it is well to bear also in mind, as Goodell has forcibly urged, that a mode of practice may be highly commendable, when adopted by a man of limited experience, without trained assistants or instruments, which would be simply criminal in a hospital surgeon, with every resource at hand. Widely as opinions and practice vary in regard to craniotomy, something will be gained, if men who differ, fairly appreciate each other's position. It is often untruly stated, that craniotomy is proscribed merely because baptism, which the mother has received, has not been administered to the child, but the honest scruple is rather, whether any one has the right to decide which of two equally unoffending persons shall be destroyed; and still more, whether crime may be deliberately committed, for the attainment of possible good. It is to be desired that craniotomy be never lightly undertaken, and that in adopting it at any time we appreciate the very grave responsibility which the operation involves; and to this end the horror with which others regard it may not unprofitably be borne in mind.

DR. BENJAMIN CUSHING remarked that practically the moral aspect of this question cannot be ignored. If, as Dr. Busey seems to think, the danger to the mother is almost the same in craniotomy and abdominal section there can be no question which operation should be chosen, but this view he did not think correct. Craniotomy in itself is neither difficult nor dangerous. The danger is in waiting until the woman is exhausted, or in the narrowness of the pelvic outlet which makes the case unsuitable for craniotomy. There are cases of slight contraction of the outlet when the child cannot pass entire, and craniotomy will reduce the labor to a normal one. A case was cited in illustration. A healthy young woman, in a first labor was seen in consultation. It being evident that nature would not effect delivery, and the child being dead the head was opened. The mother did well. Some years afterward, the same woman was again seen in consultation. She had been a long time in labor when the pains suddenly ceased and the woman was sinking. Rupture of the uterus was found and the woman was delivered by emptying the head through the foramen and turning. Still later the same woman asked Dr. Cushing to attend her in a coming confinement which was expected daily. He directed the patient to give him

early notice of labor. The os being dilated and pains well established, the head was opened and emptied and the labor reduced to a normal although hard one. The woman did well. In this case, experience having shown the probable impossibility of a living child by natural means, and the safety to the mother of craniotomy, the treatment was to be decided on moral grounds. As the speaker did not believe that the life of the mother should be put to any considerable risk to save the life of an unborn child he had no hesitation as to the proper course to follow.

DR. A. D. SINCLAIR considered it very important that we should interfere early in those cases which call for craniotomy or abdominal section. Bad results follow from either if the operation is commenced late in the case, when the woman is tired out. The operation of craniotomy is one of the oldest with which we are familiar, and it will continue, without doubt, to be performed till all men are familiar with abdominal section, and even then in certain cases, it will be wisely done. The operation will depend on circumstances, and men will do the best they can under these circumstances. A skilled operator in hospital practice with competent assistants and necessary instruments may open the abdomen with a fair prospect of saving both the mother and the child. Craniotomy is called for in cases of narrow pelvis, and when the head of the child is very large or prematurely ossified. Operators must do the best that they can, and with increased experience will reduce the demand for craniotomy to those cases which call for that operation and none other.

SIMPSON says the old operators performed craniotomy in preference to using forceps, and, in contrasting the cases with those occurring in Germany where the forceps were being frequently used, the results were bad. Now forceps and version largely take the place of craniotomy. The life of the mother is of more value than that of the child, and should be saved in those cases where both would be sacrificed if craniotomy was not performed. Early interference is an axiom that we should not lose sight of.

DR. FIFIELD said that when he began practice craniotomy was the rule, if the head was not easily reached, that is, an ear easily felt; now it was the exception. Short forceps were wholly used, and if delivery could not be effected by their aid, then craniotomy was performed. He brought the first pair of long forceps to Weymouth, where he first began practice, and since that day a decided change has taken place, and now craniotomy is very rarely done. He has not performed a craniotomy in twenty years, but should say it will be done more or less forever. When Utopia shall have become reality, and the Lost Continent shall have been found again, and both the island and the continent shall be ruled by the same laws, then and only then, shall the perforator and the blunt hook be cast into the furnace, and be known no more. In those happy lands every village shall have its hospital, every hamlet its Thomas, the very breezes will be aseptic.

Craniotomy is an operation of circumstances, and much depends upon the operator whether it will be performed. If one has not had a large experience in the use of the forceps, he may say craniotomy must be done. Even if one has had a large experience in the use of forceps we may decide that it would have been better to perform craniotomy than to have used forceps after a bad delivery shall have been shown to have resulted to the woman from the latter.

A man's conscience may sway him one way or the other, and if he is without assistants and proper instruments, he may do craniotomy and do it wisely. To a person with a quick conscience craniotomy will be a last resort. Church dogma most certainly should not influence the physician. One might be swayed by the convictions of the people interested. If they were Catholics he would enter into their feelings, if he were among Protestants then it would be different. Not that the physician would willingly sacrifice *any* infant life, but that if his conviction was that craniotomy was the safest and best, he might address himself to the task with greater celerity, without taking the question of other methods into consideration. A child to a Catholic family is always bade welcome, but it is not always so to a Protestant. No one could refuse to do craniotomy in certain cases as in some varieties of deformed pelves, etc.

Dr. M. A. MORRIS remarked that the doctrine of the Roman Catholic Church is opposed to craniotomy. The Catholic Church teaches that you shall not violate the fifth commandment, "thou shalt not kill." The end does not justify the means. You are not permitted to do an evil act that good may come of it.

Dr. Capellman who is considered an authority in the Catholic Church, teaches that each individual human being has a right to live,—the child has a right to live as well as the mother. A child *in utero* cannot be a "wilful aggressor" or violator of laws, and therefore cannot forfeit its right to live. Craniotomy is not a sure means of saving the mother; by it one life is certainly destroyed, and frequently both lives are lost. By Cesarean section the greatest number of *lives* are saved, and a greater number can be saved now than formerly, owing to improved abdominal surgery. He finds the statistics of a number of operators show that on an average over fifty-eight per cent of mothers were saved after Cesarean section, and more than fifty-eight per cent of the children were saved (Kayser 70), (Villeuve 72). By craniotomy all children are lost and many mothers.

Dr. REYNOLDS asked Dr. Morris what he should do if the woman refused to be operated upon.

Dr. MORRIS replied that it was considered the duty of the woman to consent.

Dr. SINGLAR asked the date of Capellman's book.

Dr. MORRIS said he believed the book was published in 1879.

Dr. REYNOLDS inquired if there had not been some change in the teachings of the Catholic Church, of late, regarding craniotomy.

Dr. MORRIS replied that there had been no change that he was aware of.

Dr. REYNOLDS expressed his surprise that any weight is allowed to the question of the mother's assent. From the standpoint of the last speaker, does her refusal alter the duty of the accoucheur? It may not be generally known, that according to statements apparently trustworthy, a decree lately promulgated, in response to an appeal for guidance, strictly forbids craniotomy to all Roman Catholics so long as the child is alive.

Dr. Wm. L. RICHARDSON said that he was very glad that the subject had been presented, and in so satisfactory and able a manner, for up to the present time the statement made by Dr. Buscy in his paper had gone unchallenged. The introduction of antiseptic precautions in all operations, the favorable results which are being obtained by the performance of Porro's

ovaro-hysterectomy and Thomas's Laparo-elytrotomy are rapidly limiting the number of cases in which the operation of craniotomy is demanded. There are, however, cases, as the reader has stated, in which the patient is in such a condition that no operator would feel justified in attempting either of these operations, or the more serious one of Cesarean section. To do the operation would mean to kill the patient. Nor would an unskilful operator, wholly unfamiliar with the methods of procedure, and so placed that he could not obtain either competent assistants, or the requisite means for a proper performance of the operation, be justified in attempting what could only result fatally to the mother.

There are other cases in which none of these operations, performed by the most skilful operator and with every possible convenience at hand, would be of the slightest avail. In breech presentations, where all of the child has been born except the head, and it is then discovered that the head is unusually large or preternaturally ossified, of what avail are any of these operations which involve an abdominal section? The child is no longer within the uterine cavity, and Cesarean section and Porro's operation are, of course, contraindicated, and Laparo-elytrotomy would only result in extracting a dead foetus through the abdominal wall at the imminent risk of the mother's life. So, also, in cases of the after-coming head after version, in which an unanticipated similar condition was encountered. What about cases of hydrocephalic children, presenting by the breech, as such cases are more apt to do than in the normal foetus, if the operator finds, as may happen, that he cannot deliver the after-coming head? As Schroeder states, such children, if delivered, do not live; is the attendant to stand by and see that woman die? If he does, is he not as guilty of her death as though he killed her, when, by the proper use of the means at his control, he can save her life; knowing that he does so even by destroying the child which he was also powerless, by any possible procedure, to save?

He objected to only one statement of the reader, and that was leaving the choice of procedure to the parents. The physician should always use his own judgment, and if not in accord with the wishes of the parents, his duty was to retire from the case, rather than to do what his patient or her friends desired, if contrary to his own judgment.

Dr. GREEN, of Dorchester, mentioned a case that he was called in consultation of a deformed woman with a narrow pelvis. The woman was a Catholic, and a clergyman was present, who said if the doctor intended doing craniotomy, he should step out. He had married the woman, after advising strongly against the marriage, and said she should stand the consequences. The woman's pains were strong and she was becoming exhausted. Both the woman and her husband desired that craniotomy should be done. Dr. Green, however, was unwilling, under the circumstances, to do the operation, and telephoned to Boston to an eminent practitioner of abdominal surgery to do Cesarean section. The practitioner, for good reasons, declined to operate, and advised that craniotomy should be done. The head was then opened with Dixon's perforator, and the woman delivered with the cephalotribe. She made a good recovery, but the narrator felt but small satisfaction in the operation, and was not sure that he should proceed in like manner again under precisely similar circumstances.

DR. LYMAN remarked that it would be far better for the physician to use his own conscience, to which after all he must finally be answerable, in the decision in each case, without reference to theological dogmas, Protestant or Romish. Treat each case according to its indications. It is not possible to decide on any fixed rule, but with the modern improvements in abdominal surgery, the tendency will be increased to try and save both the mother and the child. We must do the best we can in each case, governed by the varying conditions present.

DR. J. F. COUCH, of Somerville, said, when we consider the favorable results of Casarean section as compared with craniotomy, there is no justification in regarding the former in such an unfavorable light. In craniotomy, 50 per cent of the mothers and all of the children are lost. In Casarean section, according to Harris, when performed during the first twenty-four hours of labor, 70 per cent of the mothers recovered, and over 80 per cent of the children were saved. The tables upon which the opponents of Casarean section have based their arguments, were made up from operations performed in the remote ages of medicine, when antiseptics was unknown, at times by unskilled hands, and under unfavorable circumstances. According to Lusk, in one case the operation was performed six days after the membranes had ruptured, and in another case, after peritonitis had set in. Also in several cases, after forceps and version had been tried, and in one case after rupture of the uterus.

We must not deliberately take the child's life. If the mother is so constructed that it is impossible for her to give birth to her child in the natural way, *that is her misfortune*, and she must be prepared to give the child a chance to live, even though at the risk of her own life.

In answer to the speaker, who deprecated mixing theology with medicine, he said that in refusing to perform abortion upon healthy women, the former was actuated by his religious principles, and therefore mixed theology and medicine.

Regarding the case of the hydrocephalic child, and the performance of Casarean section by a country practitioner, he claimed that in the former he thought he would be justified in tapping the head, for he would not necessarily destroy life in so doing, while in the latter case, he believed that the mother's chances for life would be, to say the least, as good in the hands of the country practitioner after Casarean section, as after craniotomy. It must be remembered, that in the majority of cases, the latter operation is performed when the head is at or above the brim.

DR. WM. L. RICHARDSON said that he did not desire to enter into any discussion with either Dr. Morris or Dr. Couch of theological arguments, as he had understood the question was to be considered only on its merits as viewed from a medical standpoint. He could not help, however, wondering whether those who opposed craniotomy for these theological reasons were also opposed to capital punishment. He was at a loss to see how Dr. Couch had met the class of cases to which he had alluded; and he very much questioned the accuracy of his statistics. His statement that "if the woman is deformed it was so much the worse for her," hardly applied to those cases in which the woman was all right, but the child was deformed. Why should the woman be made to suffer for that, especially as we are unable, even if we let

her suffer, to save the child. As for his statement, that "in the case of a country practitioner, the mother's chances for life would be, to say the least, as good after Casarean section as after craniotomy," he was forced by personal experience to take an opposite view, as he had seen the latter operation admirably performed by gentlemen, with good results, who would never have attempted the far more serious and complicated operation of Casarean section.

DR. DIXON, in closing the discussion, said there were several points of considerable importance that had escaped the attention they demanded. Whether or no craniotomy should be performed more than once upon the same woman; also, whether the operation should be performed upon a woman the subject of an incurable disease; or upon a woman with a conjugate diameter of less than  $2\frac{1}{2}$  inches.

The statistics of Dr. Couch are extremely erroneous. He stated that a large percentage of mothers die after craniotomy, as many even as after abdominal section. This is not so. In my paper I have given the more recent statistics on the operation of craniotomy, and they are most favorable. Of Merkel's 100 craniotomies from 1877 to 1882 there was a mortality of only six per cent. Bidder did not lose a woman in 32 craniotomies, and Rokitsky, Jr., has published an account of 52 successful cases, occurring in Braun's wards.

Dr. Couch quoted from Dr. Bussey's paper that over 50 per cent of women are lost after craniotomy; it is well known that these statistics are erroneous. The idea that more women are saved after abdominal section than after craniotomy, is preposterous. Statistics show that when abdominal section is performed early in the case, when the woman is free from exhaustion, about 70 per cent of the mothers recovered. Statistics show that when craniotomy is performed early it is a matter of extreme rarity that even one woman is lost. Statistics also show that if the woman has an anteroposterior diameter above  $2\frac{1}{2}$  inches, and is more or less exhausted, her chances of recovery are very much better after craniotomy than after any variety of abdominal section. The tables from which I have quoted are all of recent date, and in no way go back into the "remote ages of medicine."

It is needless to reply to the statement made by one gentleman that "the mother's chances for life would be, to say the least, as good in the hands of the country practitioner after Casarean section as after craniotomy."

Theology or no theology, there is no getting beyond the point that craniotomy should be done when the pelvic diameters permit of the operation being performed, and the child is deformed so that it cannot live but a short time, even if it is born alive; when the parts of the woman are so badly swollen that the head is impacted in the pelvis; and in certain cases of breech presentation and version, all of which have been entered into thoroughly in the paper on this subject.

DR. KINGMAN exhibited the Underwood etherizer, to which reference was made by Dr. George W. Gay, in a recent discussion in the Surgical Section, and which is in constant use at the City Hospital. The apparatus consists essentially of a short metallic cylinder, partially occluded at one end by a truncated cone of the same material, the apex being directed inward. The cylinder being loosely filled with damp sponges, it is covered by a hood of moistened cotton cloth of

such shape as to fit tightly about the cylinder, expanding below to fit over the face, and above to form a balloon-shaped bag.

In operation, a portion of the expired air passes through the sponges, inflating the bag, and is then drawn back again with the act of inspiration. In its passage to and fro through the sponges, it becomes saturated with ether vapor.

The chief advantages of the instrument are:

*First.* Its extreme simplicity, there being no valves or movable parts to get out of order.

*Second.* Economy in the expenditure of ether. As the cloth bag is nearly air-tight, practically all the ether that evaporates enters the lungs of the patient, thus avoiding waste of the drug, and unnecessary saturating of the room and house with the vapor.

*Third.* The ease with which we can regulate the admission of air and the degree of concentration of the ether vapor.

*Fourth.* Cleanliness; it is far more easily cleaned of vomit or blood than is a sponge.

*Fifth.* Cheapness; it costs much less than does an ether sponge, and does not wear out.

### Recent Literature.

*Diagnosis and Surgical Treatment of Abdominal Tumors.* By SIR SPENCER WELLS, BART. Philadelphia: P. Blakiston, Son & Co. 1885.

The author in his preface says this is practically a new work, though it may be called a fourth edition of the first, published in 1865. The advances in abdominal surgery have been so great in the last twenty years, that any writer who should attempt to give a fair account of the state of this branch of surgery at the present time, as compared with that remote period, would have to virtually write a new book. Sir Spencer Wells has naturally enlarged his scope as the advances have been made, so that a book which in 1865 treated almost exclusively of ovarian tumors, now includes the consideration of the operative treatment of splenic, renal, hepatic, and other tumors, and of various inflammatory processes and conditions hitherto either unrecognized, or left alone as inoperable.

The result is a fairly complete treatise on the subject of abdominal surgery. The larger part of the book is naturally taken up with the consideration of ovarian and allied tumors. The author's views of vexed questions are too well known to need expounding here.

Listerism he adopted, understanding by that what it really means, "thorough cleanliness," and not confining it to the "spray." At about the same time he gave up the extra peritoneal treatment of the pedicle, though he evidently has still a lurking fondness for it, and considers that the introduction of thorough antiseptic precautions alone made the intra-peritoneal method possible.

It is with regret that we find him designating the removal of ovaries for other diseases than those of the organs themselves, "Batter's operation." This operation, and the other allied one so commonly called "Tait's," are such general property, and have been subject to such modification since their introduction, that it is both belittling and indefinite to continue to call them by the names of those who happened first to

perform them. There are appropriate anatomical names by which we can express definitely just what has been done, which should be used.

The second part treats of uterine and other abdominal tumors. With Sir Spencer Wells' large experience, he has met with and operated upon most of the various forms he has described. Where his own experience fails, he has drawn upon German and American records.

One fact is noticeable, the utter ignoring of Lawson Tait's work in this department of surgery, and the very small space devoted to diseases of the Fallopian tubes. He says he has only met with four cases where either one or both Fallopian tubes were so diseased as to lead to their removal; and expresses the opinion that most cases of so-called salpingitis or pyosalpinx usually recover under ordinary care and rest, without surgical treatment. In the light of what Lawson Tait has originated and demonstrated, and other surgeons in Europe and America are confirming, the inference is certainly warranted that Sir Spencer Wells has allowed his judgment to be warped by his prejudices.

The book is thoroughly interesting and readable, and embracing as it does in Sir Spencer Wells' own personal record almost the complete history of what has been done in this field, it is well worth the attention of all who are interested in this branch of surgery.

—The strong point of the Delphic oracle was the obscurity of its sayings and the possibility of attaching to them almost any desired meaning. A similar quality has, perhaps, contributed to the vitality of certain of the oracular sayings in popular use to-day. For example, the maxim so often heard, "Stuff a cold and starve a fever." The colossal absurdity of the rule in its most obvious application having become apparent to most people, it is now glozed according to the fancy of the user as follows: "Stuff a cold and (you will have to) starve a fever," that is, you will have it to treat, or on the other hand, "stuff a cold and (thereby you may be able to) starve (a. s. *scorphan*, that is, kill, abort,) a fever." The latter explanation of the phrase is probably a true one, but its correctness philologically does not imply a corresponding correctness therapeutically.

—Dr. Bradley, of Birmingham, England, who will be remembered as the victim of a charge of criminal assault by a hysterical female whom he was so unfortunate as to attend and to be left alone with for a short time, has, after seven months' imprisonment, been released by order of the Home Secretary. The judge, (Lord Coleridge) who tried the case, is said to have expressed himself as convinced of the injustice of the verdict rendered. A testimonial is being subscribed to for the pecuniary relief of, and to express the professional sympathy for the unfortunate physician.

—A writer on medical education in the last number of the *Popular Science Monthly*, commenting on the popular interest in medical topics, fostered by medical bulletins from the sickbeds of great men, and especially on the fascination which the germ theory seems to have for everybody at the present time, remarks that in the wilds of the West a cow-boy recently shot another for calling him a d—d microbe.

## Medical and Surgical Journal.

THURSDAY, SEPTEMBER 17, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$6.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

283 WASHINGTON STREET, BOSTON, MASS.

### "ENDERMOSES."

THE ancient and popular belief in the occasional occurrence of internal rashes expressive of "humors" and constitutional states, these mucous eruptions being markedly analogous to external dermatoses in their origin, clinical history, and evolution, has received the support of not a few modern pathologists, especially those of the French School. The late Dr. Noel Gueneau de Mussy was one of the most earnest advocates of the doctrine of diathetic eruptions which might affect indifferently the cutaneous or mucous surfaces; he designated under the name of *herpeticism*, that disposition of the economy called by older authors the "dartrous diathesis," and to which are assigned by Hardy these characters: hereditary influence, aptness to return, and tendency to spread over the surface of the body, and even to invade the mucous membranes, continuous with the integument.

The various affections included under this name are distinguished by their gouty or arthritic parentage, their chronicity, the itching or pain, and the ulcerations which commonly attend them; moreover, they frequently attack internal organs, either by propagation through contiguity, as when the darts of the face extend to the conjunctiva or buccal mucous membrane, or by metastasis, as when in the course of an eczema, a visceral disease is developed, and the cutaneous affection gets well.<sup>1</sup>

The late Gueneau de Mussy, in the last work which he published (*Clinique Médicale*, t. IV, 1885), devotes several chapters to internal eczemas, lichens, urticarias, etc. He professed to be always seeing cases of marked arthritic ("herpetic") diathesis, where the existence of a mucous eruption concurrently with, and in continuity with a cutaneous rash (for example, eczema of the vulva, with a herpetic condition of the internal genitals), or alternating with a skin disease (for example, severe disturbances of the digestive organs disappearing on the outbreak over the surface of the body of a

nettle rash in an arthritic subject), could only be understood as correlated manifestations of a constitutional vice; to establish the diagnosis of the mucous affection, it was only necessary to interrogate the antecedents and the external concomitant phenomena.

The herpetism may manifest itself on the mucous membranes by secretory troubles, by erosions and granulations, by intense pruritus, by a catarrhal condition of a peculiar kind. The different forms of herpetism of the neck of the womb are likely to end in granular erosions. There has been much discussion as to the nature of these granulations; they have been regarded as a budding out of the papillæ of the mucous derm like that which occurs after the application of epispastics.

Chomel was the first to consider them as a sort of vegetating lesion linked to the dartrous diathesis. According to Gueneau de Mussy, the granular condition is in certain mucous membranes the habitual expression of congestive and inflammatory processes. Most pharyngites are accompanied by the development of granulations, constituted by the tumefaction of the glandules and follicles which enter into the structure of the pharyngeal mucosa. Uterine granulations have a similar origin: they are produced by the tumefaction of the papillæ and follicles of the cervix.

There are often, according to these views, seen temporary or fugacious morbid states of internal organs which by their march, resemble certain exanthemata which behave in the same way. Pruriginous affections of the vulva may be simply mucous urticarias.

In the urticaria which occasionally succeeds the ingestion of mussels, of strawberries, etc., it would seem that the vomiting, the colic, the diarrhœa, which often complicate the skin affections, must be due to a similar internal condition; as far as the eye can penetrate the buccal cavity are seen patches of a fiery redness, which are in striking contrast with the general congestive tint of the mucous membrane.

Gueneau de Mussy asks whether, instead of appearing as a dependence on the cutaneous exanthem, the urticaria may not localize itself from the first and exclusively on the internal tegument? He answers this question affirmatively, and cites the following case in confirmation. He had just been attending a young lady who was neuropathic and migrainous, of arthritic family, who was subject to crises of cardialgia, which came on ordinarily in the night, accompanied by tympanites, nausea, hicough, vomiting. When the pain ceased, an eruption of urticaria appeared on the skin, and remained for some time. Is it not, he asks, probable that a similar fluxion had before localized itself in the digestive organs, giving rise to the morbid phenomena above described? He moreover regards it as likely that the pretended prodromes of measles, the bronchitis, the coryza, are the manifestations of an internal eruption, already contagious. This eruption, after having invaded the skin, often attacks the stomach, producing nausea and vomiting, and later still, the intestine, where it manifests itself by diarrhœa.

<sup>1</sup> Vide Hardy on the "Dartrous Diathesis," Piffard's translation: "Among certain dartrous patients affected with asthma and pulmonary emphysema, it has been noticed that the access of dyspnea is less frequent and less severe when the eruption is in full efflorescence, and, on the other hand, its returns are more frequent and grave when the external affection is cured or even notably diminished." p. 10.

These are, altogether, not simple hypotheses, for one may distinguish the morbillous spots on the pharynx during the prodromic period, and these testify sufficiently as to the nature of the process which has invaded the deep portions of the respiratory tract.

Such doctrines find more favor in France than in Germany, but there is enough to be said in their favor to afford fair ground for the differences of opinion which prevail in the two schools.

#### A PRIZE FOR A NEW INSTRUMENT FOR THE IMPROVEMENT OF HEARING.

BARON LEON DE LENVAL, of Nice, has offered a prize of 3000 francs for the best readily portable instrument constructed according to the principle of the microphone for improvement of hearing in cases of partial deafness.

This offer was made on occasion of the Third Congress for Otology, by which body a jury was appointed, in accordance with the request of Baron de Lenval, to have charge of the award. This committee consists of the following persons:—

Professor Hagenbach-Bischof, Ph. D.M.D., Chairman of the Jury (Basle); Benni, M.D. (Warsaw); Professor Burckhardt-Merian, M.D. (Basle); Gellé, M.D. (Paris); Prof. Adam Politzer, M.D. (Vienna).

Instruments of this description, intended for competition, may be sent before the 31st of December, 1887, to any one of the members of the jury. Such instruments only are admitted to compete as are completely worked out; at the examination perfection of mechanical construction, the right application of the laws of physics, and above all the power of improving the hearing will be taken into consideration. The verdict of the jury and the awarding of the prize will take place at the Fourth International Congress for Otology to be held at Brussels in September, 1888. Should none of the instruments presented be found worthy of obtaining the prize, the jury reserve to themselves the right of keeping the competition open until the meeting of the next International Congress for Otology.

#### MEDICAL NOTES.

—Dr. B. W. Richardson has recently published a summary of the anesthetics, from which we condense the following:—

Considered safe: ethyl bromide, ethyl chloride, ether, ethene (olefiant gas), ethene chloride, methyl bromide, methyl chloride, methyl ether, methine chloride, methane (marsh gas), nitrous oxide.

Of doubtful value: amylene, amyl chloride, butyl chloride, benzene (benzol), carbon disulphide, carbon dioxide, carbon tetrachloride, methyl alcohol, methylal, spirits of turpentine.

Dangerous: amyl hydride, butyl hydride, carbon monoxide, ethyl hydride. Chloroform and ethene dichloride, are regarded as useful, but requiring care. Dr. Richardson considers methyle ether to be the safest of all the anesthetics. — *Polyglotte*.

—The story comes from the West of a man so tenacious of lucre that when he swallowed a five-dollar gold piece the stomach-pump could only bring up \$4.50.

BOSTON.

—*The Medical Record* says that Prince Ludwig Ferdinand, of Bavaria, son-in-law of Queen Isabella of Spain, who obtained the degree of Doctor of Medicine at Munich last year, is now practicing at Nymphenburg, Bavaria.

—Mrs. Livermore recently delivered a lecture, being the sixth in the course to young people, on the War of the Rebellion, in the Old South Church in Boston, on the Sanitary Commission. Its work begun with the permission of the National government, but not receiving its active co-operation until after it had fully shown its reasons for being: the arrangements for distributing refreshments to the troops in transit through the Northern cities; the lodges, forty or more in number, which were free hotels, open day and night to every soldier passing on furlough, and which entertained on the average, 2300 soldiers each night; the hospital stores collected and forwarded; these, and other branches of the work of the great Commission, were graphically described. No army started into battle without a superintendent of the Sanitary Commission, and a company of agents, men and women, and wagons packed with sanitary stores. No distinction was made between the blue and the gray. Confederate soldiers were as kindly cared for as northern ones. After the battle of Antietam, for instance, there were distributed 28,763 towels, bed ticks and pillows, 30 barrels of linen bandages, 2,620 cans of condensed milk, 5,000 pounds of beef, 3,000 bottles of wine, several tons of lemons, crackers, tea and sugar. The estimated value of the sanitary stores distributed during the war was \$15,000,000, and the total amount raised and expended in the work of the Sanitary Commission was \$17,000,000.

#### Miscellany.

##### THE NEW NURSES' HOME OF THE BOSTON CITY HOSPITAL.

For a long series of years the Annual Report of the Superintendent of the Boston City Hospital has contained an appeal for a Nurses' Home, or a separate building where the nurses of the hospital could be housed and fed, apart from the hospital itself. Hitherto they have been lodged as well as possible but in a somewhat crowded manner and even then a part of the room they occupied was originally intended for, and ought to have been devoted to, patients. The greatest efficiency requires that the nurses shall be able to spend the time when off duty in properly ventilated apartments, entirely apart from the rooms occupied by the sick, and so situated that so far as possible their minds may be free from the strain to which they are subjected in their daily labors, and that recreation need not interfere with the quiet that should reign within hospital walls.

Last year authority was given and an appropriation of \$40,000 voted by the City Council for the erection of a suitable dormitory, and the completed building has, during the past week, been occupied for the intended purpose. The building stands upon the corner of Harrison Avenue and Springfield Street, separated by the latter street from the hospital grounds. It is one hundred feet long and thirty-eight feet broad and four stories in height above the basement. It is built of brick with freestone trimmings. Two iron balconies at each end serve to break the plainness of its square walls, which present a neat and solid appearance. The entrance is on the Springfield Street side in the middle of its long side. A long hall runs the full length of the building on each floor with rooms opening from it on either side. The building is heated throughout by steam, on the first floor by indirect radiation with air admitted directly from the outside, on the other floors by direct radiation. On the south side in the middle of the building on each floor are bath tubs, lavatories and water supply shut off from the rest of the building by brick walls and suitable doors. This apartment is in close relationship with the central chimney and has a separate system of ventilation. Water is not introduced by pipes into the sleeping apartments so that no defect in plumbing can introduce sewer gas, but each room is supplied with a washstand with its movable adjuncts of wash-bowl and pitcher. Ventilation has been carefully arranged, each separate room having a ventilating flue which communicates with the air shaft of the central chimney through which passes the flue from the boiler. When artificial heat is not required in the building the central flue will still be heated by a smaller boiler which will be required to furnish hot water, so that the artificial ventilation ought to be perfect during the entire year. Fireplaces in the halls and larger rooms give additional communication with the outer air.

Two iron staircases, one at each end of the building, run to the top of the building and furnish all necessary means of escape in case of fire.

The floors are all hard finished and furnished with neat but inexpensive mats.

On the right of the entrance on the first floor are two parlors, separated by sliding doors, which can be used as recitation or lecture rooms, or simply as places of meeting for the home circle. Certain aspirations for a piano are acknowledged by some of the musical ones among the nurses, and to furnish one would be a graceful act on the part of some one who desires to show appreciation of the training school. On the left of the entrance is a small reception room. On this floor are the rooms of the assistant matron who is directly in charge of the home. The other side of the corridor contains sleeping accommodations for eleven nurses.

The three upper stories are devoted entirely to sleeping rooms. Each story contains two double rooms, all the other rooms are intended for one occupant. Each room is simply but comfortably furnished and contains a single iron bedstead with wire and hair mattresses, a washstand, a chest of drawers and clothes-press, and two chairs, one of them a rocker; of course the double rooms contain these articles in duplicate. Each room has its steam heater and all are lighted by gas. Each of the three floors has accommodations for nineteen nurses. The total number in the home is sixty-eight.

The basement contains the kitchen, not yet in working order, the boilers and their adjuncts, storeroom and a large trunk room where the luggage of sixty-eight women makes a most imposing appearance.

It will be noticed that no provision is made in the home itself for sickness, in the shape of a separate room devoted to hospital purposes. Cases of sickness severe enough to require long detention in bed, will be cared for within the walls of the hospital itself.

Telephonic communication is established between the home and the central office of the hospital. No covered way exists between these different parts of the hospital, which at first would seem a disadvantage, and which certainly has its unfavorable side, but on the whole, it is thought that the necessity of passing outside the hospital walls into the open air will, on the whole, be advantageous to the nurses themselves.

#### REPORT OF THE COMMITTEE APPOINTED TO ARRANGE FOR THE MEETING OF THE INTERNATIONAL MEDICAL CONGRESS IN AMERICA, IN 1887.

The Journal of the American Medical Association contains a long report from the Committee, which recapitulates the facts of its organization and meeting in Chicago, and then proceeds to report the late meeting in New York as follows:

In August, 1885, the Chairman, the Vice-Chairman, and the Secretary, after consultation and communication with members, called a meeting of the Committee, to be held in New York City, September 3d, 1885, for the purposes of revision of the rules and the filling of certain vacancies in the list of officers of the Congress.

The Committee met in New York City, September 3d, 1885, the following named members being present: Dr. G. Baird, Dr. Robert Battey, Dr. L. P. Bush, Dr. R. Beverly Cole, Dr. W. C. Dabney, Dr. Ellsworth Eliot, Dr. A. Y. P. Garnett, Dr. S. C. Gordon, Dr. J. W. S. Gouley, Dr. J. B. Hamilton, Dr. George A. Ketchum, Dr. R. A. Kinloch, Dr. D. A. Linthicum, Dr. John S. Lynch, Dr. R. C. Moore, Dr. William Pierson, Dr. N. J. Pitman, Dr. L. A. Sayre, Dr. X. C. Scott, Dr. John V. Shoemaker, Dr. F. L. Sim, Dr. E. F. Upham, Dr. W. H. Wathen, Dr. W. C. Wile, Dr. A. H. Wilson.

The following named members were represented by proxies: Dr. E. P. Cook, by Dr. N. S. Davis, proxy; Dr. A. R. Smart, by Dr. William Brodie, proxy; Dr. J. M. Taylor, by Dr. E. P. Sale, proxy.

The Committee was called to order at 12 m., September 3d, 1885, by the Chairman, Dr. R. Beverly Cole.

The resignation of Dr. L. A. Sayre, of New York, as member of the Committee, was received and accepted, and Dr. A. Flint, Jr., of New York, was elected to fill the vacancy, and took his seat with the Committee. The resignation of Dr. Sayre was caused solely by ill health.

The following rules were unanimously adopted:

#### RULES.

1. The Congress shall consist of members of the regular profession of medicine, and of such other scientific men as the Executive Committee of the Congress may see fit to admit, who shall have inscribed their names on the register and shall have taken out their tickets of admission.

2. The dues for members of the Congress shall be

ten dollars each for members residing in the United States. There shall be no dues for members residing in foreign countries.

Each member of the Congress shall be entitled to receive a copy of the "Transactions" for 1887.

The Congress shall be divided as follows, into seven-teen Sections: I. General Medicine; II. General Surgery; III. Military and Naval Surgery; IV. Obstetrics; V. Gynaecology; VI. Therapeutics and Materia Medica; VII. Anatomy; VIII. Physiology; IX. Pathology; X. Diseases of Children; XI. Ophthalmology; XII. Otology and Laryngology; XIII. Dermatology and Syphilis; XIV. Public and International Hygiene; XV. Collective Investigation, Nomenclature, Vital Statistics, and Climatology; XVI. Psychological Medicine and Diseases of the Nervous System; XVII. Dental and Oral Surgery.

4. The General Meetings of the Congress shall be for the transaction of business and for addresses and communications of general scientific interest.

5. Questions and topics that have been agreed upon for discussion in the Sections, shall be introduced by members previously designated by the titular Officers of each Section. Members who shall have been appointed to open discussions shall present in advance statements of the conclusions which they have formed as a basis for debate.

6. Brief abstracts of papers to be read in the Sections shall be sent to the Secretaries of the proper Sections on or before April 30, 1887. These abstracts shall be treated as confidential communications, and shall not be published before the meeting of the Congress.

Papers relating to topics not included in the lists of subjects proposed by the Officers of the Sections may be accepted after April 30, 1887; and any member wishing to introduce a topic not on the regular lists of subjects for discussion shall give notice of the same to the Secretary-General, at least twenty-one days before the opening of the Congress, and such notices shall be promptly transmitted by the Secretary-General to the Presidents of the proper Sections. The titular officers of each Section shall decide as to the acceptance of such proposed communications and the time for their presentation.

7. All formal addresses, scientific communications, and papers presented, and scientific discussions held at the General Meetings of the Congress, shall be promptly given in writing to the Secretary-General; and all papers presented and discussions held at the meetings of the Sections shall be promptly given in writing to the Secretaries of the proper Sections.

No communication shall be received which has already been published, or read before a society.

The Executive Committee, after the final adjournment of the Congress, shall direct the editing and the publication of its "Transactions," and shall have full power to publish the papers presented, and the discussions held thereon, either in full, in part, or in abstract, as in the judgment of the Committee may be deemed best.

8. The official languages of the Congress shall be English, French, and German.

In the Meetings of the Sections, no member shall be allowed to speak for more than ten minutes, with the exceptions of the readers of papers and those who introduce subjects for discussion, who may each occupy twenty minutes.

9. The rules and programmes shall be published in English, French, and German.

Each paper and address shall be printed in the "Transactions" in the language in which it was presented, and preliminary abstracts of papers and addresses also shall be printed, each in the language in which it is to be delivered.

All discussions shall be printed in English.

10. The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections. This Committee shall have the power to add to its membership, but the total number of members shall not exceed thirty. A number equal to one-third of the members of the Committee shall constitute a quorum for the transaction of business.

11. The Officers of the Congress shall be a President, Vice-Presidents, a Secretary-General, four Associate Secretaries, one of whom shall be the French Secretary, and one of whom shall be the German Secretary, a Treasurer, and the Chairman of the Finance Committee.

12. The officers of each Section shall be a President, Vice-Presidents, Secretaries, and a Council.

13. The officers of the Congress and the officers of the Sections shall be nominated to the Congress at the opening of its first session.

14. The Executive Committee shall, at some convenient time before the meeting of the Congress, prepare a list of foreign Vice-Presidents of the Congress, and foreign Vice-Presidents of the Sections, to be nominated to the Congress at the opening of its first session.

15. There shall be a standing Committee on Finance, composed of one representative from each State and Territory, the District of Columbia, the Medical Department of the Army, the Medical Department of the Navy, and the Marine Hospital Service.

The Chairman of the Finance Committee shall report to the Executive Committee of the Congress.

Each member of the Finance Committee shall appoint a local Finance Committee for his State, Territory, District, or Government Department, consisting of one or more members from each Government Department or Congressional District.

Each local Finance Committee shall report through its Chairman to the Chairman of the Finance Committee of the Congress.

Dr. S. C. Gordon, of Maine, recalled his withdrawal from the Congress, which action was accepted by the Committee.

The following named gentlemen were elected to fill vacancies in the Committee of Arrangements: Dr. J. K. Bartlett, Wisconsin; Dr. J. H. Baxter, U. S. Army; Dr. George Goodfellow, Arizona; Dr. Henry Hoffman, Pennsylvania; Dr. John Morris, Maryland; Dr. J. R. Tipton, New Mexico; Dr. Thomas J. Turner, U. S. Navy. The following resolution was adopted:

*Resolved*, That the representative or representatives in this Committee from each State, Territory, or Government Department, shall organize the Financial Committees in their respective States, Territories, or Government Department.

It was decided that no person should occupy more than one position in the organization of the Congress.

It was also decided that, in the published lists of the Officers of the Congress, the names of the Vice-Presidents and Secretaries of the Congress, and the Vice-Presidents, Secretaries, and members of Councils of the Sections should be arranged alphabetically.

#### OFFICERS OF THE CONGRESS.

*President*—Austin Flint, M.D., LL.D., New York; *Vice-Presidents*—W. O. Baldwin, M.D., Alabama; H. I. Bowditch, M.D., Massachusetts; William Brodie, M.D., Michigan; Henry F. Campbell, M.D., Georgia; W. W. Dawson, M.D., Ohio; R. Palmer Howard, M.D., Canada; E. M. Moore, M.D., New York; Tobias G. Richardson, M.D., Louisiana; Lewis A. Sayre, M.D., New York; J. M. Toner, M.D., District of Columbia; the President of the American Medical Association; the Surgeon-General of the United States Army; the Surgeon-General of the United States Navy; the Supervising Surgeon-General of the United States Marine Hospital Service. *Secretary-General*—Nathan S. Davis, M.D., LL.D., Illinois. *Treasurer*—E. S. F. Arnold, M.D., M.R.C.S., New York. *Chairman of the Finance Committee*—Frederick S. Dennis, M.D., M.R.C.S., New York. *Executive Committee of the Congress*—Austin Flint, M.D., LL.D., President of the Congress; Nathan S. Davis, M.D., LL.D., Secretary-General; E. S. F. Arnold, M.D., M.R.C.S., Treasurer; Frederick S. Dennis, M.D., M.R.C.S., Chairman of the Finance Committee. *Presidents of the Sections*—A. B. Arnold, M.D., General Medicine; William T. Briggs, M.D., General Surgery; Henry F. Smith, M.D., Military and Naval Surgery; DeLaskie Miller, M.D., Obstetrics; Robert Battey, M.D., Gynecology; F. H. Tirrell, M.D., Therapeutics and Materia Medica; William H. Pancost, M.D., Anatomy; John C. Dalton, M.D., Physiology; E. O. Shakespeare, M.D., Pathology; J. Lewis Smith, M.D., Diseases of Children; A. W. Calhoun, M.D., Ophthalmology; S. J. Jones, M.D., Otolaryngology and Laryngology; A. R. Robinson, M.D., Dermatology and Syphilis; Joseph Jones, M.D., Public and International Hygiene; Henry O. Marey, M.D., Collective Investigation, Vital Statistics and Climatology; John P. Gray, M.D., LL.D., Psychological Medicine; Jonathan Taft, M.D., Dental and Oral Surgery.

#### LOCAL COMMITTEE OF ARRANGEMENTS.

(With power to increase their number.)

A. Y. P. Garnett, M.D., *Chairman*, District of Columbia; the Surgeon-General U. S. Army; the Surgeon-General U. S. Navy; the Supervising Surgeon-General U. S. Marine Hospital Service; J. H. Baxter, M.D., District of Columbia; C. H. A. Kleinschmidt, M.D., District of Columbia; N. S. Lincoln, M.D., District of Columbia; J. M. Toner, M.D., District of Columbia, and such additional members of the profession in the District of Columbia as the Executive Committee of the Congress may select.

Lists of Vice-Presidents, Secretaries, and Councilmen for each Section were named by the Committee of Arrangements, but as it was not practicable to ascertain at once who would accept the places assigned them, or who of those who had been announced in the medical press as desiring to accept positions before the present rules and organization had been adopted, as given here-

tofore, might wish to withdraw such declination, the final adjustment of these offices was referred to the Executive Committee of the Congress, and all correspondence in relation thereto was transferred to the Secretary-General of the Congress.

On motion, the Committee of Arrangements adjourned, subject to the call of the Chairman of the Committee.

JOHN V. SHOEMAKER,

*Secretary of the Committee of Arrangements.*

## Correspondence.

### LETTER FROM CHICAGO.

MR. EDITOR.—The *International Congress*, from the standpoint of the profession here, has a gloomy outlook. We cannot see how from the present situation the gathering can be in any sense international. There may be a large meeting, but if only American doctors attend, and if, as the prospect is certain, many of the most distinguished members of our own profession are absent, what is the use of a Congress at all! Drs. Lyman, Hyde, Jackson, Parkes and Senn have publicly announced that under the present organization they could not serve in the positions to which they have been appointed. Not only have a large number of the strongest men in the country declined to participate, but so large a class that the idea is growing among the profession here that the Congress will not be worth attending, that it is a fore-doomed failure as an international gathering. This feeling is heightened by the indications from abroad of a growing sentiment of dissatisfaction with our ways of doing, which is entertained by the profession of Europe, and which promises to reduce to zero, the small delegation of eminent visitors we had any reason to expect under the most favorable auspices.

And the present prospects promise little for the amelioration of the situation. We can see how some of the difficulties would disappear if one side or the other would back down,—a performance there is not the smallest chance of our seeing. The leaders of the Association movement and the company of decliners to serve, both belong to that class of mankind who do not retreat easily; they will not do it in this instance. And even if they did, and mutually did, the injury done in Europe to the prospects of the Congress are past repair. The spectacle is a humiliating one for the American profession.

The new *anatomy law* went into effect on the 1st of July. Under its provisions the colleges are quietly and easily providing themselves with material for the coming session. A section of the law, introduced into the bill by the friends of the measure to disarm criticism, provides that not more than five dollars shall be charged students for each cadaver. The law makes the refusal of an officer to deliver up the body of an unclaimed, deceased pauper, in accordance with the provisions of the law, an offence punishable by fine to the extent of five hundred dollars and imprisonment in the county jail to the extent of a year. The law is certainly one of the best, if not the best in the country, for the interest of anatomical study, and, considering the almost unanimous vote by which it was passed in the popular branch of the Legislature,—where all previous anatomical bills, with a single exception, had been killed,—there may be said to be no probability of its being repealed.

The long-continued contention at our Cook County Insane Asylum between the medical and secular management has been, it may be hoped, brought to a close by the recent re-election of the former medical superintendent, Dr. Spray. So the institution finds itself just where it was before the great efforts to purify it from its alleged scandalous condition. Whatever abuses existed under the former régime—and it cannot for a moment be doubted that abuses did exist and will continue to exist there as long as the institution is under the existing sort of political management—it will

hardly be claimed that the late management has effected much improvement. The State of Illinois has four large insane hospitals, each under the absolute control of one medical superintendent who is alone responsible to a board of trustees of three men appointed for long terms by the governor. Our county insane hospital is under the management of the county board of fifteen commissioners, elected by the people, who employ a medical superintendent and a warden to look after it? There are made from year to year more charges of jobs and frauds in the supplies to this one little concern, and of bad management within it than we hear about all four of the state institutions put together. There can be no doubt that if the county institution was under a similar simple and responsible kind of control it would be as creditable as any of the state hospitals.

Professional men—must we say especially in the West?—are very much like children, as in a general way a great many men outside the professions are likewise. If the children cannot agree to play together either they will re-

fuse to play or the outs will start a new game. Note the multiplication of medical colleges where they are not needed or in clear excess of the need. A few years ago Indiana was an amusing illustration, but wisdom has come and the colleges have consolidated. Now Detroit has just seen two colleges unite to occupy a field too small for one. Minnesota has in her rival cities two medical colleges—so that each may have a college. This is the reason; there can be no other. In Chicago, after years of effort, a college of dentistry was formed, has held three courses of instruction and is growing into notice and reputation. But our friends of the dental branch are not happy, and are making plans to be even less happy in the future. They have organized another dental college. It is somewhat doubtful if a single college at this point filled a "long felt want;" the only purpose of a second college is to furnish occupation for mind and spirit to gentlemen who have more time than is required by their regular avocation, or to furnish professorships, or to lessen the distinction of the professorships of others.

## REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 5, 1885.

40 Massachusetts towns . . . . .	—	83	74	31.86	12.05	25.11	—	6.05

Deaths reported 2,181; under five years of age 1,044; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 664, diarrheal diseases 327, consumption 200, lung diseases 121, diphtheria and croup 81, typhoid fever 50, whooping-cough 34, malarial fevers 30, scarlet fever 22, cerebro-spinal meningitis 10, measles four, erysipelas three.

From whooping-cough, New York 20, Brooklyn six, Philadelphia four, Providence two, New Orleans and Charleston one each. From malarial fevers, New Orleans 13, New York and Brooklyn six each, Philadelphia and Providence one each. From scarlet fever, Brooklyn 19, Philadelphia three, New York and Cincinnati two each, New Orleans, Providence, Lawrence, Chelsea, and Gloucester one each. From cerebro-spinal meningitis, Philadelphia four, New York three, Worcester two,

Cincinnati one. From measles, New York two, Philadelphia and Boston one each. From erysipelas, New York three. One case of smallpox reported in Boston.

In 111 cities and towns of Massachusetts, with an estimated population of 1,239,952, (estimated population of the State 1,255,101), the total death-rate for the week was 17.49 against 18.27 and 19.47 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,900,446, for the week ending August 16th, the death-rate was 20.5. Deaths reported 3,197, infants under one year of age 1,282; acute diseases of the respiratory organs (London) 162, diarrhoea 549, measles 98, whooping-cough 84, fever 46, scarlet fever 28, diphtheria 15, smallpox (London) 12, Hull one. The death-rates ranged from 12.1 in Bradford to 33.8 in Preston, Birkenhead 25.8, Birmingham 23.7, Hull

16.8; Leeds 21.8; Leicester 20.3; Liverpool 23.0; London 18.8; Manchester 30.3; Nottingham 15.5; Sheffield 24.4. In Edinburgh 18.9; Glasgow 25.7; Dublin 22.9.

The meteorological record for week ending September 5th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 5, 1885, TO SEPTEMBER 11, 1885.

McKEE, J. C., major and surgeon. Sick leave still further extended three months on surgeon's certificate of disability. S. O. 204, A. G. O., Sept. 7, 1885.

PATZKI, J. H., captain and assistant surgeon. Assigned to duty as post-surgeon, Jackson Barracks, New Orleans, La. S. O. 192, Department of the East, Sept. 8, 1885.

KANE, J. O., J., captain and assistant surgeon. Upon expiration of his present leave of absence to be relieved from duty at Willett's Point, N. Y., and to report to commanding-general Department of Texas for assignment to duty. S. O. 201, A. G. O., Sept. 3, 1885.

RICHARDS, CHAS., captain and assistant surgeon. To be relieved from duty in Department of the East and to report to the commanding officer, Willett's Point, N. Y., for duty at that station. S. O. 201, C. S., A. G. O.

POLHEMUS, A. S., first lieutenant and assistant surgeon. When relieved at Fort McMeritt, Nev., assigned to temporary duty at Presidio of San Francisco, Cal. S. O. 87, C. S., Department of California.

KENDALL, WM. P., first lieutenant and assistant surgeon. Relieved from duty at Presidio of San Francisco, Cal., and assigned to duty as post surgeon at Fort McMeritt, Nev., relieving post-surgeon Polhemus. S. O. 87, Department of California, August 31, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING SEPTEMBER 12, 1885.

There were no changes in the Medical Corps of the U. S. Navy during the week ending above date.

#### SOCIETY NOTICE.

The American Gynecological Society will hold its tenth annual meeting at the Columbian University, in Washington, on Tuesday, Wednesday, and Thursday, September 22, 23, and 24, 1885. Among the papers announced to be read are the following: "The Natural Hygiene of Childbearing Life," by Dr. S. C. Busey of Washington; "Remarks on the Use of Tarnier's Forceps," by Dr. Ellwood Wilson, of Philadelphia; "Facial Paralysis in the Infant from the Use of Obstetric Forceps," by Dr. T. Parvin, of Philadelphia; "The Genu-Pectoral Posture in the Prolonged Nausea and Vomiting of Pregnancy, with cases," by Dr. H. F. Campbell, of Augusta, Ga.; "On Two Rare Cases in Abdominal Surgery," (The Peritonitis Address), by Dr. W. T. Howard, of Baltimore; "The Care of the Perineum during Labor," by Dr. T. A. Reame, of Cincinnati; "Report of a Case of Cesarean Operation," by Dr. E. W. Jenks, of Detroit; "Puerperal Diphtheria," by Dr. H. J. Garrigue, of New York; "A Modification of Ennet's Cervix Operation in Certain Cases, with a case," by Dr. R. S. Sutton, of Pittsburgh; "Inflammation of the Parotid Glands after Ovariotomy," by William Goodell, of Philadelphia; "A Study of an Unusual Type of Puerperal Fever," by Dr. Forbaker Barker, of New York; "Perforations of the Central Tract," by Dr. J. R. Chadwick, of Boston; "Four Cases of Oophorectomy, with remarks," by Dr. Joseph Taber Johnson, of Washington. Members of the profession are cordially invited to attend the meeting.

#### INSTRUCTOR IN HYGIENE IN THE BOSTON PUBLIC SCHOOLS.

Dr. J. B. Moran has been elected Instructor in Hygiene by the School Committee of the City of Boston.

#### BOOKS AND PAMPHLETS RECEIVED.

A Complete Pronouncing Medical Dictionary, embracing the Terminology of Medicine and the Kindred Sciences, with their Significations, Etymology, and Pronunciation. With an Appendix comprising an Explanation of the Latin Terms and Phrases occurring in Medicine, Anatomy, Pharmacy, etc. Together with the Necessary Directions for Writing Prescriptions, etc., etc. By Joseph Thomas, M.D., L.L.D., etc. On the Basis of Thomas' Comprehensive Pronouncing Medical Dictionary. Philadelphia: J. B. Lippincott & Co., 1886.

The Management of Labor and of the Lying-In Period, A Guide for the Young Practitioner, by Henry G. Landis, M.D. Philadelphia: Lea Brothers & Co., 1885.

A New Bandage for Fixation of the Shoulder Girdle. By Charles W. Dulles, M.D. Philadelphia (Reprint from Medical News.)

Complete Laceration of the Perineum and Part of the Recto-Vaginal Septum, resulting from Forceps Delivery, Primary operation, Complicated with Traumatic Erysipelas. By A. B. Cook, M.D., Louisville, Ky. (Reprint, Gaillard's Medical Journal.)

Laryngoscopy and Rhinoscopy in the Diagnosis and Treatment of Diseases of the Throat and Nose, by Prosser James, M.D. 4th edition, enlarged. N. Y.: Wm. Wood & Co., 1885.

Medical Education: a Paper read before the Philadelphia County Medical Society, Sept. 24, 1884. By Henry Leffmann, M.D., D.D.S. (Reprint.)

A Plea for the Medicinal Use of Pure Alcohol and Alcoholic Mixtures of Known Composition in Preference to Ordinary fermented liquids. By Henry Leffmann, M. D. (Reprint from the Polytechnic, July, 1885.)

Von Ziemssen's Handbook of General Therapeutics. In seven volumes. Vol. II. Antipyretic Methods of Treatment by Prof. C. Von Liebermeister. Antiphlogistic Methods of Treatment by Prof. Th. Jürgensen. Epidemic, Endemic and Hypodemic Administration of Medicines by Prof. A. Eulenburch. With twelve Illustrations. New York: William Wood & Co., 36 and 38 Lafayette Place, 1885.

Tubercular Meningitis as it occurs in Children. With an Appendix of Illustrative Cases and two Chromo-Lithographs. By Martin Oxley, M.D., Consulting Physician to the Liverpool Infirmary for Children. (Reprint from the Liverpool Medical-Chirurgical Journal, July, 1885.) Edinburgh: Printed by Neill & Co., 1885.

Laws of Maternity. By Nathan Allen, M.D., L.L.D., of Lowell, Mass. (Reprint from the New England Medical Monthly.)

## Lecture.

### THE INFLUENCE OF THE VASO-MOTOR SYSTEM IN THE PRODUCTION OF CERTAIN SYMPTOMS.

A CLINICAL LECTURE, DELIVERED AT THE PHILADELPHIA HOSPITAL,

BY EDWARD T. BRUEN, M.D.,

Physician to the Hospital and Assistant Professor of Physical Diagnosis in the University of Pennsylvania.

REPORTED BY WILLIAM H. MORRISON, M.D.

GENTLEMEN: I shall to-day call attention to the relations of the vaso-motor nervous system to certain diseases and the importance of recognizing the influence of these vaso-motor nerves, in the management of special symptoms which complicate many forms of disease which are met with both in hospital and in private practice.

The first case which I shall present in illustration of this subject is the patient on the table, a man about thirty-five years of age, admitted to the hospital ten days ago. He stated that he had been drinking for some time past and that just before admission had taken a severe cold. He was quite delirious at times and had, when first seen, a temperature of 105°. The physical examination of the chest gave the ordinary signs of pneumonia at the right base, and subsequent examination lead us to believe that this was pleuropneumonia. In other words, we had not only dullness, bronchial breathing, and increased vocal resonance and fremitus, but we also had a greater degree of dullness than is common in pneumonia, even flatness, and at times friction sounds were heard over the consolidated area. Examination of the heart at this time showed that its impulse was deficient in force. The radial pulse was deficient in volume although the pulse rate was not high, about 100. It was rather curious that with a temperature of 105°, the pulse rate should be so low. During the progress of the case, the delirium increased, and it was with difficulty that the patient could be restrained in bed. Within three or four days the delirious condition changed to one of lethargy. The pupils were contracted and the patient lay in a slight stupor. During the stage of delirium, we had used for a single twelve hours, small doses of opium. This was given to control the delirium which we considered to be a complication of the disease dependent on a condition of cerebral exhaustion incident to the man's habits. Ten drops of laudanum only had been taken every three hours, and in all only about thirty drops were given. I do not think, therefore, that the subsequent stupor could be attributed to the opium.

Finding this condition of delirium and stupor with the physical signs of pneumonia, it became an interesting problem to determine whether the cerebral condition was dependent on the pneumonia or whether there was some other condition disturbing the function of the brain to account for the symptoms. I did not regard the delirium in this case as due to the pneumonia, for the following reasons: Firstly, because the pneumonia was at the base. When delirium complicates pneumonia, the inflammation is usually at the apex. Secondly, the area of consolidated tissue was not very large, only one lobe being affected. Thirdly, the man had been a heavy drinker. We therefore ascribed the delirium to the chronic alcoholic habit rather than to the pneumonic condition. The pathological condition

we regarded as one of passive congestion of the brain. The effect of alcohol on the system is depressing. Large amounts of it usually produce distinct cardiac weakness and depression of the nerve centres. We had in our patient in addition to the weak heart, the depressing effect of alcohol manifested upon the cerebral and vaso-motor nerve centres, as the cause of the delirium. In many cases of chronic alcoholism, where there is delirium alternating with stupor, the condition is connected with a state of passive congestion of the brain. If the brain were examined under these circumstances, it would be found that the pia mater was injected and the evidences of venous repletion more marked than in active congestion. The brain would be soft and oedematous and excess of fluid would be found in the ventricles, and in grave cases effusion beneath the membranes.

Recognizing this condition, our treatment was twofold. In the first place, we wished to stimulate the heart and circulation, but although the heart was weak it could not be treated with alcohol because the patient's stomach was very irritable, and vomiting was a constant symptom. This symptom was associated with a tongue which was brown and dry in the middle and did not present the glazed and shining appearance which would lead one to suppose that the patient had been suffering from gastritis; neither was there tenderness over the region of the stomach. The vomiting appeared simultaneously with the delirium, and we connected the two events, regarding the vomiting as a symptom of cerebral anæmia rather than of any local condition.

As we were unable to administer food by the stomach, we resorted to that treatment which is appropriate in chronic alcoholism, that is, the use of food by the rectum. We gave this man, every six hours, four ounces of pancreatized milk. These injections were alternated with the injections of beef tea into which an egg had been stirred. This was continued until the stomach became retentive. We also poured brandy over cracked ice and caused it to be administered.

The main element of the treatment is, however, yet to be considered, and it is for that purpose that I have brought the case before you this morning. Some years ago, an English physician, Dr. Chapman, called attention to the fact that if applications of heat and cold were made to the spine, the vaso-motor system in general and also the sensory nerves were somewhat influenced. He, like most originators of any system of treatment, exaggerated the scope of this valuable measure, claiming, for instance, that by the use of hot and cold applications to the spine one could cure diseases as cholera, sea sickness and the like.

About a year ago my attention was called to the use of this same treatment in certain cases of eczema which occurred in the practice of a Boston physician. This gentleman treated a number of severe cases of eczema with the application of ice bags alternating with hot water bags to the cervical and dorsal spine. The theory on which these applications were made was this. On the one hand cold applied to the spine has a decidedly benumbing effect upon the sensory and spinal centres, and thus peripheral sensibility was lessened, and the measure also has a tendency to determine the blood from the spine and cause its accumulation in the peripheral vessels. On the other hand, hot applications to the spine tend to determine blood to the spine, and associated with this effect there is a

contraction of the peripheral capillaries from vaso-motor action, and thus is accomplished a reduction of the amount of blood in the peripheral capillaries and arterioles. Basing his treatment on these facts the Boston physician found that when cold was applied to the spine, the itching and painful sensations were relieved, but by the increased peripheral circulation it appeared that as much would be lost as had been gained. By a simultaneous judicious application of heat and cold to the spine however, he produced great amelioration of the symptoms in his eczema cases, and cured several obstinate cases without other treatment.

These results put me on the track of what I consider an important means of treating certain conditions associated with the disorders of circulation. One of these was present in this case. I applied to the back of this man's neck, the actual cautery and produced the scars which you see. It is common to apply blisters under these circumstances, but by means of the actual cautery we employed counter-irritation in a more efficient form. We also applied hot water bags to the cervical and dorsal spine. These were applied for three hours, then omitted for the same length of time, and reapplied. We counted upon the influence of this application upon the vaso-motor system to relieve the passive congestion of the brain, favor a more active circulation, and thus remove the symptoms which we ascribed to this condition.

The results of these measures were, I think, very striking. Without other treatment, the patient was decidedly relieved within thirty-six hours. The mental condition began to improve, and from that time the recovery has been uninterrupted. In forty-eight hours from the beginning of the treatment we were able to give food and stimulants by the stomach.

The treatment of pneumonia in this hospital is usually based on the free administration of stimulants, and with excellent results. It consists in the administration of whiskey, carbonate of ammonia, and digitalis. We used these drugs to combat the pneumonia, but as these measures are quite familiar, I do not especially refer to them at this time, but will confine myself more especially to the treatment of the cerebral condition in chronic alcoholism.

In many such cases, then, we observe that the treatment with counter-irritation in the form of the actual cautery and the application of hot water, would be of great service. One of the most successful methods of treatment in chronic alcoholism, added to the above, is by the use of food and diffusible stimulants. Some twenty years ago opium was considered the most efficient drug in delirium due to alcoholism, and was freely given to produce sleep. At the present time there is a great hesitation in using opium in such states, for the respiratory centre once benumbed, it is oftentimes with great difficulty that the patient is kept alive while the effects of the alcohol are passing off. We now regard the delirium of alcoholism as a condition which will frequently pass off spontaneously, if the patient's strength can be maintained; consequently the most satisfactory treatment of these conditions is the administration of food in concentrated form, as beef tea, frequently repeated, together with such drugs as capsicum. Capsicum is a diffusible stimulant and stomachic tonic which takes the place of the alcoholic stimulant of which the patient is deprived. It should be administered in the form of the tincture in quite large doses, twenty to twenty-five minims, every two or three hours.

Sleep should be secured either by combining with the capsicum a certain amount of chloral or by giving chloral separately. Ten or fifteen grains of chloral may be given with capsicum every two hours until from sixty to seventy-five grains are taken. The other plan is to give the capsicum by itself and give the chloral in five grain doses every five minutes until thirty grains are taken. After an interval of two hours these five grain doses may be repeated. Given in this way, the possible danger of depressing effects of chloral on the circulation are avoided and the total amount required is less than when fifteen or twenty grain doses are given every two hours.

Opium should only be used in those cases in which the demand for sleep is urgent and where the delirium is so extreme that the patient is becoming exhausted, or after the food, capsicum and chloral treatment has failed. In these cases the judicious use of a small amount of morphia hypodermically may control the symptoms. Morphia or opium is, however, a dangerous drug in these cases and should only be used with great caution under the circumstances mentioned. With these remarks let me turn to another patient who also serves to illustrate the influence of the vaso-motor nervous system upon the manifestation of symptoms.

#### EXOPTHALMIC GOITRE.

The next patient has been seen by the class on a previous occasion, but I wish you to note her condition at this time so that you may compare it with her condition a month or two hence after we have pursued a plan of treatment to which I shall refer. This woman has the three salient symptoms which differentiate her disease as exophthalmic goitre, or Graves' disease. We recognize the lustrous protruding eye-balls, the enlarged thyroid and the rapid action of the heart. There is also general tremulous movement of the body and limbs. With the excited action of the heart there is also heard on auscultation a blowing systolic murmur. The symptoms of this disease developed two years ago. Up to that time she had been in fair health. The period of the onset of the present symptoms was the time of the menopause, and as an evidence of the wave of irritation which passes over the nervous system at that time, she has developed this condition.

The three symptoms which have been noted are characteristic and distinguish this case from simple enlargement of the thyroid body or goitre. This is pre-eminently a disease dependent upon disorder of the vaso-motor and cardiac nervous systems. The protrusion of the eyes is supposed to be due to dilatation of the blood vessels in the orbit, or to the contraction of the involuntary muscular fibres in the orbital membrane which covers the speno-maxillary fissure, or both causes combined. The enlargement of the thyroid is due to dilatation of the blood vessels which are liberally supplied to that gland, though increased formation of tissue in its substance may occur. The excited action of the heart which is usually unconnected with organic disease is to be explained by a stimulation of the accelerating nerves; and this as well as the alteration of the nerves of the orbit has been ascribed to disease of the lower cervical sympathetic ganglia, in which increased connective tissue and diminution of ganglionic cells have been observed. Exophthalmic goitre is a disease which is very much increased by momentary excitement. I recall the case of a patient almost cured of this affection who saw an individual

suddenly die in the opposite bed. In a few hours, the whole series of symptoms had returned: a similar outbreak often attends the menstrual period. Graves' disease is especially common in woman, and between the ages of twenty and thirty, also in persons poorly nourished anæmic and of a nervous temperament. All these are facts going to show that it is a disease peculiarly dependent upon disorders of the circulating nervous system.

The treatment of this disease is only successful after a prolonged use of the apætic measures and improvement is often connected with a change in the physical condition of the individual. If the affection develops near the menopause, after that period, the disease recedes. In sewing girls and poorly nourished young women, the affection may disappear as the nutrition is improved, but in many cases the symptoms never entirely vanish.

The most successful methods of treatment have been first, the use of iron in some assimilable form, for instance the more soluble salts which can be kept up for a long time without interfering with digestion; second, the use of *Digitalis*; third, the use of electricity. Iron is used until the condition of the blood is manifestly changed. The *Digitalis* is useful through its stimulative effect on cardiac innervation and upon the vaso-motor nervous system. The electricity applied to the spine in a descending current, either in the form of the constant or the slowly interrupted Faradic current, or one pole may be applied to the nape of the neck, and the other over the sides of the thyroid tumor. The latter remedy is especially designed to increase the nutrition of the vaso-motor nerves. The occasional resort to bromides and arsenic may be necessary.

I propose in this woman to try the treatment with hot water bags applied to the dorsal and cervical spine. A long spinal bag filled with hot water will be applied from two to three hours every morning and for the same length of time every afternoon. In connection with this, we shall employ suitable constitutional remedies to improve the crasis of the blood. I do not see why, if the emotion of fright or of joy can so profoundly influence the vaso-motor system as to bring on the symptoms of this condition, it would not be possible to have improvement by acting on these centres in some positive way as can be done by the application of heat.

I would like to add another fact in this connection which is, in fever the temperature can often be lowered as much as a degree by rubbing up and down the spine, the hands being lubricated by oil applied to the spine. This is another argument to show that the vaso-motor nerves can be influenced in this way, since we know that elevation of temperature is in part a neurosis connected with nervous disturbances near the vaso-motor centres.

We shall try this treatment thoroughly, and in a month I shall bring her before you in order that you may see the result.

#### ŒDEMA DUE TO VASO-MOTOR DISTURBANCE.

Here is another case in the same line. As you see, there is marked swelling of the legs. This man is forty-seven years of age, and states that he was perfectly healthy until seven days before admission, when this swelling made its appearance. When first observed, the swelling affected the face and upper extremities as well. The urine has been examined and albumen

found, but the microscope reveals no evidence of renal disease. We have been unable, on repeated examination to discover either casts or epithelial cells. The appearance of the patient is well nourished and of good color, is also against this view. He asserts positively that he never had any swelling before.

He is equally free from any cardiac lesion. The heart is normal in its valvular structure, for although the force of the cardiac action is weakened, there are no evidences of fatty degeneration.

On examining the lungs, there are heard in different places some harsh and also some moist râles, but no such general distribution of râles as would lead us to suspect bronchitis. There is but little cough and no expectoration, no fever. The inference is that there is a certain amount of œdema of the lungs as is plainly evident in the limbs.

I think that this dropsy may be reasonably ascribed to a condition of deficient vaso-motor tones. The fact that there is such a condition, is undoubted. It has been shown experimentally on animals, for if the vena cava is compressed to a certain extent, dropsy will not occur unless the sciatic nerve is cut, for the veins and lymphatics are able to take up a certain amount of effusion. If the sciatic nerve is cut, dropsy occurs, for the sciatic is a mixed nerve containing vaso-motor filaments. Exudation then occurs after its section beyond the ability of the absorbents to remove. This has been shown to be due to the section of the vaso-motor filaments, because if the sympathetic filaments which enter the sciatic are cut in the lumbar region, there will be no paralysis of motion, but the limb will become rosy and warm and there will be dropsy, just as occurs when section is made lower down, but in which there is also motor-paralysis.

Then another fact. It is known that if a hypodermic injection be given to an individual suffering with a serious brain lesion, there is a likelihood of suppuration, and bed-sores occur in persons whose nervous system is affected, for instance, in paralytics. This is due to interference with the trophic or vaso-motor nerves, as the case may be. In the same way, it has been shown that water injected into the cellular tissue of the frog will be absorbed so long as the brain and spinal cord remain intact. If these are damaged, the water will not be absorbed. With these facts before us, we cannot but admit that vaso-motor dropsy is possible. It becomes our diagnosis in this case because we can exclude renal, hepatic, and cardiac disease, and also any of the forms of anæmia. While at first it involved all the tissues, it is at present limited to the most dependent parts, the limbs and the lungs, since the patient habitually reclines on his back.

It is obvious that if the diagnosis be correct, rest and nerve tonics should be sufficient to relieve the patient. I should be willing to limit the treatment to these measures if time were no consideration, but in our patient, the mechanical effects of the vaso-motor dropsy are inconvenient, and moreover, the action of the heart is entebled by his indulgence in alcohol, we desire, therefore, to relieve the dropsy as soon as possible. The best remedies would be either *Digitalis* or caffeine. Of the two, I should prefer caffeine, because besides being a cardiac tonic, its effects upon the nervous system are stimulative, and it has a decided diuretic effect. Two grains of caffeine, three times a day may be given. This should be combined with an equal quantity of benzoate of sodium to render the mixture clear.

If necessary, heat may be employed by the pharmacist in making a clear mixture, the bulk of which might be this elixir of orange, or syrup and water. About twelve or fifteen grains per day, of caffeine should be the limit of dose, but much smaller amounts are often sufficient. Abroad, as much as thirty grains a day have been given without damage.

Has caffeine any bad effect? It has one. In the treatment of a case of dropsy in which I advised caffeine, it quickly removed the effusion, but in four or five days the patient began to exhibit that kind of delirium which is seen in connection with belladonna poisoning. This is the only bad effect that I have noticed, and these symptoms have been most infrequent. It (caffeine) is a cardiac stimulant; it is not emulative, and does not injuriously affect the kidneys. The unpleasant cerebral effect is easily avoided with a little care, and the disturbance of the nervous system can be quickly removed by stopping the administration of the drug.

This patient will be kept in bed and the caffeine administered, and four weeks from to-day, I shall show you the result.

(Four weeks later.) I have the satisfaction to-day of showing the case of Graves' disease, and you observe that the improvement of the general symptoms has been marked. The exophthalmos and enlargement of the thyroid have manifestly lessened. One may feel sufficiently encouraged by the results to persevere with the treatment, for we may reasonably conclude that two months' treatment will produce even more positive effects. You will remember that before using the hot-water bags, many other plans of treatment had been tried and signally failed.

I can also exhibit one case of vaso-motor dropsy as cured, and the patient will be discharged to-day.

### THE TREATMENT OF CHRONIC BRIGHT'S DISEASE.<sup>1</sup>

BY ISAAC L. DANA, M.D., PORTLAND, ME.

*Professor of Pathology and Practice, Medical School of Maine.*

A FEW considerations seem naturally to claim attention as preliminary to that of treatment.

By chronic Bright's disease I mean the affection, first described by Dr. Richard Bright, in 1827, characterized by albuminuria, dropsy and uremia, the urine usually containing, also, casts of the renal tubules, and showing a deficiency of urea. The acute form of the disease, so often seen as a complication of pregnancy, or a sequel of scarlet fever, and which so commonly terminates in recovery, is not included within the scope of this paper.

In its anatomical relations chronic Bright's disease is a complex affection, at least three forms of structural disease are usually reckoned as underlying it. The first of these is that of tubal, or desquamative nephritis, the inflammation beginning in, and for a time being confined to the epithelial cells, which line the tubules, later becoming diffuse, and producing the so-called large white kidney. The second is that of interstitial nephritis, the inflammation commencing in the connective tissue of the organ, and finally inducing the small,

hard, contracted, cystic, or gonty kidney. The third is that of amyloid degeneration, the small arteries and capillaries of the kidneys being first attacked. One common result obtains, at last, in all the forms, that is, destruction, or atrophy of the parenchymatous elements of the kidneys, with consequent failure of function.

It may be well also to glance at some of the most prominent theories, that have prevailed in explanation of the disease, as having had an important influence upon the philosophy of the treatment. These theories have been brought forward chiefly in answer to two questions, namely, first, how is the large escape of albumen by the kidneys to be accounted for? second, at what point in the system does the disease originate? By some the escape of albumen in the urine has been regarded as the result of a true eliminative action on the part of the kidneys, by which the blood is happily relieved of an accumulated excess of albumen. By others, on the contrary, it has been looked upon as a disastrous leak of the kidneys, due to the double condition of abnormal blood pressure within the renal capillaries, and of impaired vitality of their walls, the blood being believed to be thereby robbed of its serum-albumen, and impoverished. By some the kidney lesion has been regarded as primary, and the albuminuria, the dropsy and the uremia as consequences. By others the blood has been looked upon as the primary point of trouble, with the albuminuria, the dropsy and the kidney lesions as secondary. By yet others it has been held that the starting point of the disease is somewhere in the nerve centres, that it is of ganglionic origin. They claim that the disease is primarily a neurosis, and that the albuminuria, the dropsy and the renal troubles are of secondary development. The alleged fact that albuminuria, as well as glycosuria, can be induced by irritation of certain portions of the medulla is brought forward as giving plausibility to this view. While the theories have differed widely as to the point at which the morbid process commences, they are well agreed to this, that structural change in the kidneys constitutes the most characteristic pathological lesions.

In a disease so generally fatal in its issue as chronic Bright's disease, the question of the value of treatment naturally arises in the mind. Does it make much difference how it is treated, provided no mischief be done, or, whether it be treated at all? I believe that good treatment is of immense value. By the exercise of constant and intelligent supervision, the adoption of a suitable general plan, and the adoption of measures of relief to the shifting phases, and emergencies of individual cases, not only can much suffering be prevented or relieved, but great prolongation of valuable and effective life may sometimes be gained. It is then alike the privilege and the duty of the physician to throw more of hopefulness and cheer into the treatment of this disease than is generally done.

The first duty of the physician is to investigate each particular case by itself. This is as important as it is for the teacher to study the peculiarities of individual pupils. It is not only desirable to determine the form of the disease present, its stage of development, as shown by the symptoms, and by chemical and microscopic examination of the urine, and any peculiarities of manifestation, but also to inquire into its probable causation. He must therefore make himself acquainted with the personal and family history of the patient, as

well as with the previous history of the case. A broad principle of treatment, laid down by Beale, is to let the kidneys rest, as far as possible, and throw the work upon the skin, the bowels and the lungs.

I will endeavor to present the items of treatment under the following specific indications.

I. One of the most important indications is to avert, or reduce hyperæmia, and inflammation of the kidneys. With this end in view a uniform and sufficient warmth of the surface of the body should be maintained. In this disease, and also where predisposition to it exists, when the large amount of blood normally present in the cutaneous capillaries is reduced by chilliness of the surface, a corresponding hyperæmia of the renal capillaries is very likely to occur. In a case recently under my observation, of the typical parenchymatous nephritis form, the man owned, and steadily worked upon a farm, located upon a narrow neck of land projecting out from the Maine coast into the sea, and commonly swept by cold and damp winds, often sudden and severe. Frequently, when covered with profuse perspiration, his skin would become chilled with the winds, and he had himself noticed an apparent connection between these experiences and the development of his trouble. A moderately warm and equable climate is a great advantage. A sufferer from this disease, who is so favorably circumstanced as to be able to avail himself of different climates for different seasons of the year, so that he can have the benefit of free out-of-door life all the year round without risk of becoming chilled, has his chances of prolonged and comparatively comfortable life thereby greatly increased. Woolen undergarments should be worn, thick enough to ensure warmth without inducing sweating. A flannel night-gown is advisable in cold weather. In acute exacerbations of the disease, attended with increased heat, the patient should be kept in bed, between blankets, for days, or weeks. The importance of maintaining a uniform warmth of skin, in this affection, does not seem to be fully appreciated by the average practitioner. Local applications to the lumbar regions are useful, such as leeching, or cupping, followed by warm fomentations, especially when a sense of heat, and heaviness has arisen, with scanty secretion of urine. I have found advantage in large packs. Several thicknesses of towels may be used, large enough to thoroughly envelop the small of the back, and come round somewhat freely upon the abdomen. These should be wrung out in tepid water, covered with oiled silk, or impervious paper, and bound firmly on with a flannel swathe. A small blanket, folded once, may then be wrapped, and firmly pinned around the body below the waist. These, having been worn for the night, are removed in the morning, the skin is sponged with cold water, and rubbed dry, and a flannel swathe is worn for the day. Mild diluent diuretics are sometimes called for.

II. A second indication is to unload the obstructed uriniferous tubules of their accumulations. The thrown off and altered epithelial cells, transuded fibrine, extravasated corpuscles, and fatty debris, sometimes in the form of casts, frequently occlude the tubules, and add to the existing disability of the kidneys. Simple diluents, and mild diuretics are then needed, such as cream of tartar water, and pure natural waters like the Poland spring water. They should be drunk freely, and, by preference, on an empty stomach, so as to be quickly absorbed, and pass off through the kidneys.

III. A third indication is to build up the blood, and promote nutrition. Whether, or not, the blood is ever the starting point of the morbid process in the system, it is certainly true that the peculiar anæmic look of the patient is often the first thing that arouses in the mind of the physician a suspicion of the true nature of the disease, while, in the advanced stage, the blood is constantly found impoverished and depraved to the last degree, and utterly unfit to maintain healthy nutrition. Of the large class of building-up remedies I will mention, as specially useful, the *mistura ferri et ammonii acetatis*, cod liver oil, and malt. Judicious and persistent use must be made of this class of remedies.

IV. A fourth indication is to improve the condition of the nerve centres. The importance of this indication is specially plain in the cirrhotic form of the disease, occurring in painters, and others, who have been exposed to poisoning by lead. Here the iodide of potassium, the dose of ten to twenty grains, conveniently administered in half a tumblerful of Vichy water, may be given three times a day for long periods of time, with markedly good results. The same method is applicable to cases of syphilitic origin, or occurring in systems specifically infected. In such cases the corrosive chloride of mercury, in small doses may be substituted for the iodide of potassium for the period of a few weeks from time to time, with advantage. In some of the cirrhotic cases of unknown origin, I have found great benefit from the use of the chloride of gold and sodium, as suggested by Bartholow, in the average dose of the twelfth of a grain, in pill form, after each meal. I have seen periods of marked improvement of general condition, and special relief of distressing nervous symptoms follow its use. Arsenic, in small doses, and the hypophosphites are sometimes useful.

V. The fifth indication is to promote the elimination of urea from the blood. In order to appreciate the importance of this indication we have only to remember that uræmia constitutes the chief danger of the disease, a fatal apoplectic seizure being occasionally its first revelation; or, to seize to mind the fearful sufferings of the paroxysms of uræmic dyspnoea, uræmic headaches and uræmic convulsions. Here we must mainly rely upon vicarious evacuations by the skin and bowels, and I believe that sudorifics are the most valuable class of remedies. Profuse diaphoresis may be induced by hot air and hot vapor baths, and by the internal administration of various drugs, of which *jaborandi* is by far the most valuable as an eliminator of urea from the blood. But the means, which I have found at once the most efficacious and convenient, is the hypodermic injection of pilocarpine. I have resorted to this method many times with the best results. The dose used is generally a quarter of a grain, the patient being in bed between blankets, and I usually find the entire surface of the body covered with a profuse sweat within the space of five minutes. When the process of diaphoresis is over the skin may be wiped dry, and fresh clothes put on. The amount of the secretion is enormous, and the elimination of urea has been shown to be large. Great relief of the uræmic symptoms is often obtained by the daily use of this method for a series of weeks. I have seen, in a case still fresh in my mind, headache, dizziness, dyspnoea, unrest, marked impairment of vision, and heart irritability so largely and rapidly subside as to raise a doubt in the mind of friends, and even of the attending

physician, as to the correctness of a diagnosis, unhappily fully confirmed by the later history of the case, and, at last, by the autopsy. I recommend the plan to my professional brethren, cautioning them to be sure to get an article of good quality.

VI. A sixth indication is to evacuate dropsical accumulations. For this purpose mechanical methods are sometimes useful, such as acupuncture of the legs, prepuce, labia, etc., or a short incision over one of the malleoli. Tapping of the abdomen is generally to be avoided in renal dropsy. Erysipelas is specially liable to follow operative methods in this form of dropsy. Hydrogogue cathartics, which are often so well borne, and so satisfactory in results in cardiac dropsy, are neither so safe nor so useful in the dropsy of Bright's disease. Sometimes, however, resort must be had to elaterium, in suitable doses and combinations. Sometimes making temporary use of the remaining powers of the kidneys, diuretics may be given, especially the infusion of digitalis with the iodide of potassium, or cream of tartar. But I believe that in this disease, not only for the elimination of urea but also for the evacuation of dropsical accumulations, the hypodermic use of pilocarpine is not only one of the safest, but also one of the most effective measures at our command. It is a good plan to alternate the various methods, laying the burden of vicarious service alternately upon the different organs. The Basham's mixture, above mentioned, besides being useful as a blood restorer, often acts as a gentle tonic-diuretic.

VII. A seventh indication is to sustain the heart. It has been shown by Johnson, and others, that in the inflammatory forms of the disease the walls of the small arteries and capillaries are very constantly thickened, and their calibre diminished. Indeed, it has even been proposed to call the disease an "arterio-capillary fibrosis." Associated with this vascular affection, if not indeed caused by it, is found hypertrophy of the left ventricle of the heart, which very generally, at last, undergoes fatty degeneration and dilatation. It is therefore a matter of great importance to save the heart if possible from all strain. No over-exertion of body or mind should be allowed. Excitements of all kinds should be avoided, and tranquility of mind should be promoted. Digitalis and strychnine are perhaps the two drugs most used, from time to time, to strengthen the heart's action.

VIII. My last indication is to palliate the suffering of this distressing disease. The methods for this are in large measure involved, and have been mentioned under other heads. As much of the distress doubtless arises from uremia, so the most lasting relief is that which comes from the elimination of the urea. I will mention a few items here. In the fits of dyspnea prompt relief is sometimes obtained from the hypodermic injection of the quarter of a grain of morphia with the hundred and a twentieth of a grain of atropine. The nitrite of amyl quickly affords relief, in some cases, a few drops being put upon a handkerchief and held to the nose. The same use of morphia and atropine is often useful in convulsions, restlessness, and general nervous disturbance of the advanced stages of the disease. For the headache and dizziness a couple of grains of sodium in a teaspoonful of syrup of lactophosphate of calcium may be given three times a day, and, for the insomnia, thirty grains of bromide of potassium, with seven or eight grains of chloral at bedtime. For the uræmic coma I have

found the hypodermic use of pilocarpine by far the most effective remedy.

For diet, as a rule, any articles of plain and simply cooked food may be allowed which the appetite inclines to and the stomach is able easily to dispose of. In some cases advantage is found in a restricted diet of milk, skim-milk, or butter-milk.

Again, in closing, I would mention by way of emphasis, that while chronic Bright's disease is, at least, very generally fatal, yet the fatal issue is not necessarily a speedy one, and that years of comparative comfort and effectiveness may sometimes be added to valuable lives, by constant watching and judicious treatment.

## A RARE CASE OF INTESTINAL MALFORMATION.

BY C. P. HARRIS, M.D., OF NEWBURYPORT.

THE case which I am about to report is unique in my experience, though a few similar cases are on record. Gross (Surgery, Vol. II, p. 684) says of such intestinal malformations: "The rectum, instead of terminating at the anus, occasionally, though very rarely, opens by a narrow canal into the urinary passages, generally at the posterior part of the urethra, or at the *bas fond* of the bladder, a short distance below the insertion of the urethra, the former mode of communication being more frequent. The malformation is almost peculiar to males, and generally proves fatal within a few days after birth, on account of the small size of the recto-vesical outlet not allowing a sufficiently free discharge of fecal matter. To this rule, however, an exception occasionally occurs; thus in a case which I attended with Dr. Kempf, and in which I made a very deep incision without reaching the bowel. The child survived six weeks, passing daily a little fecal matter through the urethra. An uncle of the child had lived in a similar condition for thirty years."

Mrs. A. B., of Newburyport, while temporarily staying in Boston, gave birth in May, 1884, to a male child which was found to have an imperforate anus. Dr. H. M. Jernegan was called in to render surgical assistance; he dissected upwards in the ischio-rectal fossa in the direction of the rectum for some distance without finding the bowel, gave up the search, and closed the wound. The next day the infant began to pass thin faeces with its urine, every such passage giving pain. The child seemed for a time to thrive; had frequent fecal motions per urethram attended with much straining and distress. At the age of five months, symptoms of obstruction of the bowels set in; for five weeks nothing but urine was passed by the urethra; the abdomen was tympanitic and painful; for several days all nourishment was vomited, these symptoms all passing away with the return of copious fecal discharges along with the urine.

I first saw the child in October. It was then a puny, pale, delicate infant; weight, fifteen pounds; lay most of the time like a limp, flaccid body in its mother's arms; could not raise itself or sit erect; took its food from the bottle with avidity, and seemed at times playful, but had frequent straining urethral passages of thin faeces, which were generally of a normal color, and curdy.

In the Spring of the present year, I found the condition of the infant not materially changed. There had

been little growth; there were no teeth. The pain during a fecal operation was very great, the child writhing in agony. These discharges were quite frequent, averaging one an hour, day and night. The indication for anodyne treatment was urgent, but opiates were, for obvious reasons, unadvisable. I directed that the bowels should be kept free, and the stools liquid by manna and magnesia, and the pain relieved by hyoscyamus, conium, chloroform water, and ether inhalations. The consent of the family to a surgical operation (left lumbar colotomy, or opening the bladder at its lower posterior portion and establishing a fistulous communication with the exterior through an artificial anus), could not be obtained. August 1st, the child sank from the prostration of the hot weather and teething, dying at the age of fifteen months. The autopsy was performed by Dr. H. F. Adams and myself, only the abdomen being examined. The intestinal canal was normal, except at the lower portion; there was entire absence of the rectum, and the descending colon, with its sigmoid flexure dilated and distended, and forced over to the right side like a letter V, opened by a narrow, rigid tube an inch and a half in length by half an inch in diameter, into the prostatic portion of the urethra, just behind the pubic arch. The bladder, which was not at all dilated, and to all appearances was healthy, contained a quantity of liquid feces. The urethra was injected, swollen, and dilated to such an extent, that a good-sized catheter could easily be made to enter the bladder. Nothing abnormal was detected in the other abdominal organs.

Such cases as the above have a physiological as well as a medical interest, and seem to be a reversion to a primitive type of vertebrate life.

## REPORT ON NERVOUS DISEASES.

BY S. G. WEBBER, M.D.

### ARTHRITIS IN ATAXIA.<sup>1</sup>

JOINT disease in connection with locomotor ataxia. A discussion before the Clinical Society of London.

Dr. Moxon strongly opposed the view that the joint disease in locomotor ataxia is a trophic lesion depending upon disease of the cord or nerves. He seemed to consider that the cause of the changes in the bones was due to rheumatism; a joint affected with slight rheumatic inflammation is persistently used and hence serious changes in structure and loss of substance results. He thought that if the patients did not go about on their ataxic joints, keeping up a continual irritation, the originally chronic simple rheumatism would not result into an aggravated, unrepairing, irritative, severe, and therefore strange and peculiar disease of the joint. This so-called Charcot's disease began as a common rheumatism and ended in extensive disorganization, only after long experience of spasmodic irregularity of action in the presence of a wholly broken-down condition of the protective system; when there is anaesthesia of the joint so that the muscles are not inhibited from acting and thus moving the diseased surfaces over each other. He asked the Society, before deciding upon so obscure a matter, to make it clear, to what extent it was probable that the later stages of a joint inflammation would be aggravated by insensibility and spasm, even when that inflammation com-

menced as common rheumatism. He thought there was too strong a tendency to refer new or strange phenomena to the nervous system, to the trophic influence of the nerves, incidentally alluding to the ease with which bones, ribs especially, may be broken in some patients who are not insane. He characterized Professor Charcot as a clinical observer than whom none had ever brought a more powerful imagination in the service of science nor had a better observing talent.

Henry Morris reported two cases, one of lesion of knee joint, which improved greatly by rest. The other was the case of a man who had a leg in a condition of elephantiasis, both ankles were affected and there were perforating ulcers on both feet. After death the posterior tibial nerve on both sides was found diseased, an enormous thickening of the epineurium, and scarcely any change in the perineurium; the nerve fibres were scattered very sparsely, there were only large nerve fibres; the smaller were almost entirely absent.

Mr. Herbert Page referred to the difference between the slow wearing away of the bone in cases of rheumatic disease and the rapid destruction seen in Charcot's cases, during an exacerbation of other symptoms, at gastric crises. He thought regard enough had not been paid to the clinical aspect of the subject.

### SPINAL SCLEROSIS.

J. Babinski (Recherches sur l'anatomie pathologique de la sclérose en plaques et étude comparative des diverses variétés de scléroses de la moelle. Archives de Physiologie, norm. et path., Feb. 1885, p. 186) has used Weigert's coloring fluid in the study of sclerosis, combining with it also, in some sections, carmine. He concludes that locomotor ataxia resembles sclerosis in patches much more closely than it does secondary systematic sclerosis.

The habitual absence of secondary degenerations in disseminated sclerosis is not a derogation of the Wallerian law. This apparent anomaly arises from the fact that the axis cylinders are generally preserved in disseminated sclerosis. In cases where they are not entirely preserved, there arises, as in other destructive affections of the central nervous system, secondary degenerations, whose intensity is in proportion to the number of axis cylinders destroyed.

The destruction of the medullary sheaths in disseminated sclerosis far from being dependent upon a mechanical cause, upon a compression of the nerve fibres by the newly formed connective tissue, is rather allied to a vital phenomenon and arises chiefly from the nutritive activity of the cells of the neuroglia and the lymphatic cells. The nature of the degeneration of the nerve fibres, analogous to that which is noticed in the central end of a divided nerve near the section, the persistence of a large number of denuded axis cylinders, the intensity of the changes in the walls of the vessels, the frequent complete disappearance of the myelin in the centre of the islets, form histologically the essential features of disseminated sclerosis. The nature of the degeneration of the nerve fibres, analogous to that which is observed in the peripheral end of a divided nerve, the absence of denuded axis cylinders, the slight severity of the vascular lesions, the persistence in the midst of the sclerosis of a large number of fibres with myelin, gives the secondary systematic sclerosis its distinctive characteristics. By the possible persistence of a certain number of denuded axis cylin-

<sup>1</sup> British Medical Journal, December 29, 1884.

ders, by the severity of the vascular changes, by the sometimes complete disappearance of myelium in the sclerosed columns, tabetic sclerosis resembles, histologically, disseminated sclerosis rather than secondary sclerosis.

#### POLIO-MYELITIS ANTERIOR ACUTA.

David Drummond (On the Nature of the Spinal Lesion in Polio-myelitis Anterior Acuta, or Infantile Paralysis. *Brain*, April 1885, p. 14) had the fortune to examine the cord of a girl five years old, who died six or seven hours after the commencement of an attack of infantile paralysis. At the autopsy the cord between the third and fourth cervical nerve presented appearances suggesting red softening. After hardening and preparing the anterior cornua, anterior white column, and the middle and anterior portions of the posterior cornua were seen to be intensely congested, the capillaries distended with blood corpuscles, many spots of extravasation were seen. The anterior cornua seemed most seriously affected. The cells of these cornua were swollen, granular and rather ill-defined; the majority had lost their nuclei, their processes were no longer visible. The cells that presented the most obvious changes were more or less surrounded with dilated and blocked capillaries and minute haemorrhages; some seemed to be imbedded in blood corpuscles. In most sections one loin seemed to have suffered more than its fellow.

This is the earliest observation after the beginning of the disease, and confirms the theory that it is of an inflammatory nature. The author also notices that a sudden congestion, not passing into inflammation will explain many cases of temporary spinal paralysis in infants.

The necessity for early antiphlogistic treatment is emphasized, as cold to spine and affected limb, leeches, hypodermic inject of ergotin.

#### SPINAL CONCUSSION.

Duméril and Petel (Commotion de la moelle épinière. *Arch. de Neurologie*, Jan., 1885) report a case of injury from a fall upon the head, with an autopsy, showing lateral sclerosis and atrophy of cells of the anterior cornua. The earliest symptoms were rather those found in severe cases of so-called concussion of the spine.

The whole subject of spinal concussion is reviewed, and the authors conclude that

(1) Concussion of the spinal cord ought to be admitted in the present state of medical science.

(2) It may be the origin of subsequent inflammatory lesions.

(3) These inflammatory lesions may present the form of systematic myelitis.

(4) Concussion may exist in a latent state and be revealed only by secondary disturbances, varying from simple temporary congestion to incurable sclerosis.

#### LESIONS OF NERVES IN MAL PERFORANT.

Pitres and Vaillard (Altérations des nerfs périphériques dans deux cas de mal perforant et dans quelques autres formes de lésions trophiques des pieds. *Archives de Physiol. norm. et path.*, Feb., 1884, p. 208), have had an opportunity of examining the nerves in two cases of mal perforant. They find that the lesions of the peripheral nerves which cause the plantar mal perforant often extends far above the imme-

diate vicinity of the ulceration. These may attack all the nerves of the foot and of the leg, they may even ascend to the nerve trunks in the thighs.

The extension of the neuritic alterations explains the frequent coincidence of the mal perforant with certain sensitive trophic, vaso-motor, or secretory disturbances which have been often noticed at a greater or less distance from the ulcer on the foot (anæsthesia), analgesia, lancinating pain, sclerosed induration of the skin, abnormal pigmentation, muscular atrophy, gangrene, local sweating, etc., extending over the whole skin of the foot, and even of the leg.

The relations of mal perforant with peripheral neuritis have been now confirmed in a large number of histological examinations. The objection raised by Michard, according to which the examinations would be without value because in normal conditions the nerves of the foot contain many altered fibres, is not well founded. In the normal condition, in both youth and adults the integuments of whose feet are entirely healthy, the nerves of these extremities have exactly the same structure as the peripheral nerves of other parts of the body.

On the other hand, the terminal filaments of the nerves of the feet are often altered in persons who have corns, bunions, ungual dystrophies, etc., on the feet. All these lesions of the skin and its annexes appear to be true trophic disturbances allied to the existence of a previous slight and partial neuritis, as mal perforant is allied to the previous existence of a deep and extensive neuritis.

Vigouroux (Maladie de Thomsen et paralysie pseudo-hypertrophique. *Arch. de Neurologie*, Nov., 1884) reports a curious case in which both Thomsen's disease and pseudo-hypertrophic paralysis occurred together, each disease showing its own peculiar characteristics uninfluenced by the other.

#### EPILEPSY.

Bourneville and Brion (De l'emploi du curare dans le traitement de l'épilepsie. *Arch. de Neurologie*, Jan., 1885, et seq.) tried curare in the treatment of twenty-one cases of epilepsy at Bicêtre. The formula used was

Curare . . . . .	8 grammes.
Alcohol . . . . .	10 aa.
Glycerine . . . . .	90
Distilled water . . . . .	6 drops.

This was used hypodermically. The maximum daily dose was six centigram.

The results they obtained were very different from those reported by some observers. Of twenty-one patients attacked with the most varied form of epilepsy, some adults, some children, treated by this means during three, ten months, or more, they found only one who derived any important benefit from the treatment, another was slightly benefited. In a third, though the attacks were not diminished in frequency their severity was less. They conclude that these results are not very encouraging, and think that curare ought not to be considered as a useful agent in the treatment of epilepsy.

#### NEURASTHENIA.

Anjel (Experimentelles zur Pathologie und Therapie des cerebralen Neurasthenia. *Arch. f. Psych. u. Nervenkr.*, vi, 3, 1884, p. 618) has experimented with reference to the condition of the bloodvessels during

cerebral activity. He considers that every irritation, acting upon the brain, fright, joy, etc., or longer continued mental work is attended with a change in the volume of the blood-vessels. This change is the only objective correlative of cerebral irritation which can be measured by our present appliances.

He recognizes that there are sources of error in his apparatus, which he has tried to avoid.

The method employed was to enclose the forearm in a glass cylinder full of warm water, then by a carefully regulated and delicately acting system of tubes and levers very minute changes in the volume of the forearm were registered on smoked paper.

This plethysmograph showed that in health every emotion and every sensory impression caused a decrease in the volume of the arm which continued during the period of mental activity. Hence he concludes from Moosé's experiments, there is corresponding increase in the amount of blood in the brain.

When the experiment was tried upon neurasthenic patients the author was surprised to find that the arm showed no change in volume during mental activity. The disturbance caused by fitting the apparatus produced such extreme dilatation of the cerebral vessels that it was necessary to wait until the normal condition had been at length restored. Then it was found that very slight mental activity caused the volume of the arm to vary. The diminution continued only a short time, and was followed by an increase; these alternating changes were repeated several times at irregular intervals and continued after the mental activity ceased.

A slight increase in the vascular tone, as after a meal or a glass of wine, caused the change in volume to become more permanent as in health.

The author found that long-continued pain caused the vessels of a healthy person to react like a neurasthenic patient for a short time after cessation of the pain. The same effect was produced by tobacco-smoking in a person not accustomed thereto.

He draws conclusions for treatment, that it is necessary to remove the patient from his former surroundings and activities; to care for slight changes in his daily routine of life so as to give variety. There is no drug which will remove each symptom, an appropriate well-ordered regimen is most successful.

A quiet, pleasantly situated locality should be chosen. The great exhaustion of the nervous system must be compensated by a corresponding ingestion of food. Five or six meals a day are recommended, and that food should be taken in the morning before rising. It is also advised that patients should sleep a part of the time during the day.

#### ETIOLOGY OF NERVOUS DISEASES.

Ch. Féré (Nerve troubles as foreshadowed in the child. *Brain*, July, 1885, p. 230) has written upon an important subject in considering the predisposition to nervous disturbance dependent upon heredity and early disturbances of development, whether during fetal life or in early infancy. After briefly opening the subject by alluding to the influences which may thus early disturb the nervous health, he says: "Before we can admit the accidental origin of a nervous affection, it is necessary to eliminate not only the presence of any direct or indirect hereditary condition, whether similar or transitory, but also that of any

disturbance of evolution capable of bringing about a defective development of the nervous system.

After mentioning many of the slighter departures from the normal condition and influences which may predispose to subsequent nervous trouble, he says: "It is only after a thorough inquiry into the existence of such organic or functional disorders and into the neuropathic trouble of childhood, that one can determine the value of the exciting causes of nervous diseases. Otherwise there is a danger of attributing to traumas or to infectious diseases an importance which they do not possess in reality.

"When we take into account the hereditary tendencies and the early manifestations which betray a disturbance of evolution, we shall see that it is not the predisposition which it is necessary to prove, but it is rather the absence of this predisposition which is to be doubted in the history of nervous diseases."

### Hospital Practice and Clinical Memoranda.

#### CASE OF OPIUM-POISONING. MASSACHUSETTS GENERAL HOSPITAL.

SERVICE OF DR. E. S. WHITTIER.

REPORTED BY CHARLES W. TOWNSEND, *House Officer*.

This patient was brought to the Hospital at 10.30 a.m., August 24th, 1885, with the history of having taken one and a half to two ounces of laudanum about an hour before, in a fit of despondency following a week's debauch. Examination showed a muscular, well-nourished man, 29 years old, completely unconscious; pupils moderately contracted, giving no reaction to light; respirations stertorous, eight in a minute; pulse strong, regular, 110. Apomorphia gr.  $\frac{1}{10}$  was at once given subcutaneously, and repeated in four minutes without effect. A strong Faradic current was continuously applied to chest and limbs, causing at first a little grooming from the patient but no other signs of consciousness. At 11 a.m. two pints of warm water were introduced into the stomach by a stomach pump and washed out, smelling strongly of laudanum, of a brown color and free from particles of food. At this time, whenever the electric current was stopped, respirations became slower and more superficial, and the face cyanotic. Atropia sulph. gr.  $\frac{1}{10}$  was given subcutaneously at 11.10 and again at 11.30 a.m.; the pulse becoming more rapid, 118, and remaining strong and regular; pupils were slightly less contracted after the second dose of atropia. Respirations remained from six to eight in a minute. Stomach washed out again at 11.20, and a third time about midnight, the last time the washings coming out nearly clear. A pint of strong coffee was then injected through the stomach tube.

At 12.30, pulse was 110-116, strong and regular, respirations were reduced to five, and the face growing gradually more cyanotic, notwithstanding the constant application of the strong Faradic current over diaphragm and chest muscles. Artificial respiration—Sylvester method, was then resorted to at frequent intervals, as often as indicated by cyanosis, with the effect of restoring the red color to the face, the battery being constantly applied to the legs at the same time. From 1 to 2 a.m., artificial respiration was made continuously, as an omission of this was followed by rapidly-increasing cyanosis, and no attempt at respira-

tion, or but a feeble one, after the lapse of a quarter to half a minute. At 2 A.M. the patient took fairly deep respirations, five in a minute, of his own accord, and was once noticed to move his lips a little; but from that time till 3.15, artificial respiration had to be resumed at frequent intervals as often as cyanosis showed itself. At 3 A.M., gr.  $\frac{3}{16}$  of sulphate of atropia, and two grains of citrate of caffeine were given subcutaneously. From 3.15 to 5 A.M., respirations were five in a minute, long and deep, and sufficient to aerate the blood, as shown by the good color of the patient. At 5 o'clock, the patient first showed signs of consciousness, opened his eyes, turned his head and tried to speak, and under the constant stimulus of the battery, of slapping and talking, he was so far roused at 6 A.M., as to be able to walk between two men. The walking was continued at intervals till 10.30, when he was put to bed in the ward, the respiration being then 12, pulse 110, temperature, 102.2° and pupils of normal size. Patient vomited freely shortly after returning to consciousness on being given some coffee to drink. Catheterised at 12.30 and 5.30 A.M., about  $\frac{5}{16}$  of urine being obtained the first time and  $\frac{5}{16}$  the second; he passed of his own accord about  $\frac{5}{16}$  at 3 P.M. The skin remained warm from the first, covered with slight perspiration on entrance, which disappeared until he began to walk.

The patient was mildly delirious till 1 P.M., after which he seemed rational, but was nervous and tremulous, and developed a violent delirium tremens two days later, on the evening of which day he suddenly died, apparently from rapid heart failure.

## Reports of Societies.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

MAY 9, 1885, the President, DR. A. D. SINCLAIR, in the chair.

DR. F. H. DAVENPORT reported the following case of

#### POST-PARTUM HÆMORRHAGE.

In August, 1884, I was asked to attend Mrs. A. in her confinement, which was expected within a few weeks. The physician who had attended her in her two previous confinements wrote the following: "On both occasions she came near dying of uterine hemorrhage. She faints as soon as the shoulders are born; and when you withdraw the body, which I found I had to do with my hands, as there were no more pains, the blood rushes out like a good-sized hydrant stream. I used ergot, ice introduced into the uterus and upon the abdomen, compression through abdomen and kneading. Raised the foot of bedstead, gave hypodermic injections of whiskey, turned out clot after clot, and in about three hours obtained a firmly contracted uterus. Ether acts badly upon her uterine contractions."

August 22d I was summoned at seven o'clock in the morning. I found that she had had slight pains since early morning, and they were now beginning to be more frequent and harder. The progress, however, was slow, and it was not until twelve o'clock that the dilation of the external os was fairly under way. At eleven o'clock I gave ten grains of quinine, and an

hour later ten more. As soon as the os was fully dilated and the head coming down I gave a drachm of fluid extract of ergot, and repeated the dose possibly ten minutes before the birth of the child. The patient nobly seconded me in my desire to have her take as little ether as possible and only inhaled a few whiffs during the last pain. The child was born without any difficulty, and the uterus contracted firmly, giving me ample time to tie the cord and give the child to the care of the nurse.

With the very next pain the placenta came away, and this was followed by an alarming hemorrhage. The uterus became perfectly flabby under my hand placed on the abdomen, and I immediately allowed a stream of hot water, 120° F., to flow into the uterus from a fountain syringe. This was followed by contraction of the uterus which, however, was only temporary. I repeated the hot water, and finding this did not permanently check the flowing I alternated that with the introduction of ice into the uterus. After a few repetitions of the alternate heat and cold the uterus remained firmly contracted, and in from half to three quarters of an hour after the birth of the child the patient could be moved from the cot on which she was delivered to her own bed. Only once, soon after the first gush, did the patient feel at all faint, and that was but momentary. She remarked that this was the only time she had ever heard the first cry of her baby. She did well until about the eighth day, when she had a rise of temperature, due undoubtedly to a slight phlebitis of the left leg. That delayed her getting up until the end of four weeks, and her leg was then somewhat stiff and painful.

I attributed the less profuse post-partum hemorrhage in this confinement to the use of quinine two and three hours before the birth, ergot as soon as the os was fully dilated, and the alternate application of heat and cold to the uterus.

Several German writers have reported cases where hot or cold water alone having failed, the alternate application of both at short intervals has been followed by a prompt cessation of the hemorrhage.

DR. RAYNOLDS agreed with the reader in placing a high estimate on the value of the alternate use of heat and cold in checking post-partum hemorrhage; he believed, too, in the efficacy of electricity, and thought one should have a battery in readiness at every labor. He said that the late Professor Buckingham was thought to have saved two lives by the timely use of electricity in post-partum flooding. Ergotinine, in doses of five to ten drops, administered subcutaneously, was said to be of extreme value, and not injurious to the subcutaneous tissues.

#### THE DIAGNOSIS OF PREGNANCY.

DR. GREEN read the report of a case which had presented unusual difficulties of diagnosis, the report having been prepared by Mr. H. S. Durand, of the Harvard Medical School, who had immediate care of the patient. The case may be briefly summarized as follows:—

A negress, forty-three years of age, applied at the Boston Lying-in Hospital for out-patient attendance in her seventeenth labor. As the woman believed herself to be pregnant, and gave all the rational signs of pregnancy, no physical examination was made until the element of time came in to throw doubts on the assumed diagnosis. The woman was sure, however,

that she felt vigorous fetal movements, and there had been a progressive enlargement of the abdomen. A careful physical examination was now made, with the following result: The abdomen was symmetrically enlarged to the size of pregnancy at full term, and the umbilicus protruded somewhat. The breasts were large and secreted a watery fluid. The abdominal wall was very thick. Percussion gave tympanitic resonance over the sides and to a less degree in front, but no more than might be expected from intestines distended with gas lying over the gravid uterus. On palpation no well-defined uterine tumor could be made out; but movements resembling those of the fetus in utero were very well marked. The fetal heart was not heard; but the supposed fetal movements were very audible through the stethoscope. Thus far the physical examination threw no improbability on the diagnosis of pregnancy; but examination per vaginam revealed a cervix in no degree softened, and it was decided that the woman was in all probability not pregnant, unless still in the early months. Dr. W. L. Richardson kindly saw the case with Dr. Green, and agreed that the condition of the cervix ruled out advanced pregnancy, although the peculiar pseudo-fetal movements led him to examine the case with extreme care. As the patient objected to taking either it was impossible at that time to determine the size of the uterus; but a course of cathartics and cathartics reduced the flatulent condition of the intestines and enabled Dr. Green to detect the fundus just above the symphysis pubis. A sound was then passed and the uterus shown to be of normal depth. It was then clear that the case was that of a woman who had passed the menopause, and who, being in vigorous health, has grown progressively obese. The peculiar movements were doubtless caused by a discharge of flatus from one coil of intestine to another.

Dr. RICHARDSON said that the peculiar movements simulating fetal motion made him hesitate in reaching an opinion: he had never felt such movements before, except in a case of pregnancy. His diagnosis was based, like Dr. Green's, on the vaginal examination: the condition of the cervix ruled out pregnancy, unless it was still in the early months.

Dr. REYNOLDS asked the opinion of members as to the value of bi-manual examination in diagnosing pregnancy in the early months.

Dr. CHADWICK said he could usually detect pregnancy at the third month and sometimes at the second month by the bi-manual examination. He introduced his index finger into the anterior cul-de-sac and his second finger into the posterior cul-de-sac, and depressed the uterus with his other hand: in this way he made out the axes of the uterus and from their relative changes formed his opinion, aided by his appreciation of the consistency, mobility and weight of the organ. In the early months the uterus has usually a certain globular shape, which differs from the form of a uterus enlarged by a fibroid. In cases in which the uterus is retroverted and he is able to replace it, if it fails to retrovert in a week, he assumes the woman to be pregnant, even if the uterus is not sufficiently enlarged to enable him to judge by its size.

Dr. RICHARDSON said he believed that the ease of making a bi-manual examination and the accuracy of its results were greatly enhanced by having the patient lie on her back with her legs extended, whereby the abdominal muscles are relaxed: if the patient draws

up the legs and rests the heels on the bed or table, she instinctively supports herself in a manner with her heels and thus renders the abdominal muscles tense.

Dr. F. H. DAVENPORT said that in the majority of cases he was able to determine the existence of pregnancy by the bi-manual examination at the third month, and in many cases at the second month. This was much easier when the patient had been under treatment before, and the size of her uterus was known. When that was the case a very slight increase in size could be readily made out. He thought that an increase in the thickness of the uterus, antero-posteriorly, was the first thing noticed, rather than an increase in the length. In the early months the examining finger feels the body of the uterus through the vaginal cul-de-sac in every direction more easily, and can make out the more globular form. There is also a peculiar elastic feel to the body of the pregnant uterus which is characteristic. It is difficult to describe, but is easily recognized after some experience. It is probably the same sign which has been observed by some Continental writers and spoken of as a softening of the lower segment of the uterus.

Dr. STROSC said he felt very sure that pregnancy existed when he detected the peculiar, elastic resistance without a sense of fluctuation.

Dr. GREEN spoke of the importance of being able to recognize by vaginal examination the existence of pregnancy in the early months in hospital cases and others, in which corroborative evidence, known only to the patient, is purposely withheld from the physician in the hope that his manipulations, or local treatment of some genito-uterine affection, may produce abortion. He alluded to a case in point which he had recently seen at the City Hospital: a woman of suspicious appearance, complained of certain symptoms which might fairly be attributed to a displacement of the uterus, but denied all symptoms of pregnancy. Examination disclosed a retroverted uterus, apparently somewhat enlarged, the fundus imparting a peculiarly elastic feeling to the examining finger. On account of this sensation of elasticity no treatment was instituted, but the patient was kept under observation, and soon after the uterus was found to have undergone spontaneous reposition: it was then very easy to determine the existence of pregnancy from the shape and size of the uterus.

Dr. C. E. STEDMAN asked how much value was to be attached to the violet color of the introitus in the diagnosis of pregnancy.

Dr. CHADWICK said the peculiar violet tint was of great value as a diagnostic symptom when it was present; but its absence did not, of course, exclude pregnancy.

Dr. RICHARDSON had seen the blue color in women who had borne many children.

Dr. CHADWICK said the blue coloration of the plura was of a different tint and was differently distributed. He had seen the blue coloration to which Dr. Richardson had reference in cases after excessive coitus. The peculiar violet tint, which he thought was of value in the diagnosis of pregnancy, was of deepest intensity, or perhaps only perceptible, on either side of and behind the meatus.

#### PERIPHERAL PLACENTA.

Dr. F. H. LOWARD, present by invitation, reported the following fatal case, and showed the uterus and its appendages:

The history of the patient from whom this uterus comes is briefly as follows: She was thirty-four years old, well-built, of robust constitution and plethoric habit. Had been married a little over a year. Had never had any serious illness. Up to a week ago was in perfect health, being at that time about six and one-half months advanced in her first pregnancy. During last Saturday afternoon she felt a slight pain in the epigastrium. In the evening, while visiting neighbors, this pain became so severe that she was obliged to return to her home and go to bed. At one o'clock Sunday morning she had a convulsion, no premonitory symptom, other than the constantly increasing epigastric pain, having shown itself in the meantime. At 3 A.M., she had a second convulsion, without having fully recovered from the unconsciousness produced by the first. She was coming out from this second convulsion at 3.30 A.M., when her physician arrived. Pilocarpine was immediately injected under the skin and profuse diaphoresis quickly followed. A tablespoonful of urine was drawn from the bladder and found to be heavily loaded with albumen. She had voided no urine since the previous afternoon. The pilocarpine was repeated once or twice at intervals and continuous sweating kept up by blankets and bottles of hot water. The patient remained in a state of coma and had a third convulsion at 7 A.M., lighter than the first two, neither of which had been severe. At 8.15 coma continuing, with increasing stertor, cyanosis and a sledge-hammer pulse, sixteen ounces of blood were withdrawn from the arm. The patient improved in color and the pulse became less bounding; but otherwise the bleeding had no immediate effect upon the coma. There were no further convulsions, however, and during the forenoon the patient's condition improved so that at 2.30 P.M., when I first saw her, in consultation, she was sufficiently conscious to open her eyes when spoken to, and had been able to be lifted on to the vessel in the hope that the bowels would move.

Although fully determined before reaching the house that the uterus should be emptied at once, on seeing the improvement of the patient I was led to change my decision and agreed that so long as improvement continued it was wisest to wait, standing ready to interfere at the first return of unfavorable symptoms. As the bowels had failed to respond to various cathartics administered during the forenoon, a quarter of a grain of elatrium was advised and given by the mouth. Nutrient enemata were given at intervals through the afternoon, and the patient apparently was gaining. The appearance of improvement, however, was illusory, as there was no increased secretion of urine. At 6 P.M., the patient had a slight convulsion, the fourth in order, and the first since 7 A.M. At 8.30 P.M., I was again summoned. The patient was again unconscious, the pulse thready and collapse threatening. Brandy was given subcutaneously and by the rectum, and dilatation of the cervix was begun at once. The cervix yielded rapidly to digital dilatation, and in fifteen minutes fetus and placenta were delivered. Profound collapse followed the emptying of the uterus, and was the result of shock, there having been no hemorrhage. Subcutaneous injections of ether and of brandy every fifteen minutes with postural treatment and hot bottles restored the circulation, and finally brought the patient out of her collapse, which lasted four hours, during most of which time no pulse was perceptible at the wrist.

The next morning the patient had a fair pulse, was able to recognize her husband and to take nourishment by the mouth. Still the kidneys refused to act. A tablespoonful of urine drawn from the bladder showed under the microscope large quantities of fatty degenerated, renal epithelium; numerous hyalin casts (plain and waxy); large numbers of highly granular, with here and there an epithelial cast; spiculated crystals of uric acid. During the afternoon coma again came on, and the patient remained unconscious from this time, death ensuing Tuesday morning at 11 o'clock, thirty-eight hours after delivery. At the autopsy, made by Dr. Gannett, twenty-four hours after death, both kidneys were found to be in a state of marked parenchymatous nephritis. Other organs normal. The uterus and appendages present nothing pathological. When asked how long before death the process in the kidneys, as shown by autopsy, had developed, Dr. Gannett replied that it had probably been going on for a week at least. I will add that the urine, which had been examined by the physician in charge once a month during the pregnancy (as a matter of routine and not because renal trouble was suspected) never showed an abnormal constituent; and the last examination was made two weeks before her death.

Dr. LOMBARD said he would like to submit for the Society's consideration two questions: first, whether it is advisable to give ether to a comatose patient, when it is known that the kidneys are affected and the brain also, if the patient is perfectly still; second, whether it is advisable to empty the uterus without delay when the eclamptic seizure occurs between the fourth and seventh months; of the propriety of this treatment after the seventh month there is less doubt.

Dr. INGALLS could not see why ether should be used when the patient was comatose.

Dr. HODGSON said he controlled the first symptoms of restlessness with chloroform, which he thought was preferable to ether; but he saw no reason to give an anæsthetic when the patient was in a state of coma; he had no fixed rule about emptying the uterus.

Dr. STROSS said that if the patient moved when touched, he would use ether; and he believed in emptying the uterus immediately.

Dr. REYNOLDS spoke of the great value of ether in eclampsia and said it was his firm conviction that convulsions would not recur if all restlessness were quieted by the judicious use of the anæsthetic; he would therefore secure to the woman peace and tranquility, using only a small amount of ether when the patient was quiet, but continuing its use for hours, if necessary, even when the patient was comatose. In reply to a question by Dr. Brown, he said he would use ether notwithstanding the uræmic condition, until it was found that its use was harmful under such circumstances. Regarding the propriety of emptying the uterus, Dr. Reynolds said that when a second or third convulsion has occurred the time for waiting has passed, and the child is to be disregarded; even if viable there is little hope for the child after several convulsions; he was therefore in favor of emptying the uterus at this juncture, whatever might be the time of pregnancy.

Dr. C. E. SEIDMAN, in reply to a question by Dr. E. P. Gerry regarding the value of the subcutaneous use of morphia in eclampsia, said that the morphia treatment was recommended by Dr. G. W. Gay, and he had himself used it with success.

Dr. F. W. Goss was reminded by the case reported of a fatal case occurring under his own observation in which excessive epigastric pain was the chief prodromal symptom: he had reported this case to the Boston Society for Medical Improvement.<sup>1</sup>

#### THE MICROCOCCI OF VAGINAL DIPHTHERIA.

Dr. H. C. ERNST, by invitation, showed a culture upon "agar-agar," and microscopic preparations of a micrococcus obtained by the courtesy of Dr. W. L. Richardson, from a case of diphtheritic vaginitis at the Boston Lying-in Hospital.

#### RHODE ISLAND MEDICAL SOCIETY.

THE usual Quarterly Meeting was held in Providence, September 17, 1885, the President, Dr. O. C. Wiggins, in the chair.

Drs. Clarence B. Davis and Frank L. Wyman, of Providence, and Dr. John J. Baxter, of Woonsocket, were elected Fellows.

In accordance with notice given by Dr. E. T. Caswell at a previous meeting, the By-Laws regulating admission to the Society were discussed and amended. Hereafter, "examinations for admission to this Society shall be conducted by a Board of five members, to be appointed by the President at the annual meeting. Each year, the senior by appointment shall drop out and his successor shall be appointed for five years. Examinations shall be held in the month of April of each year, and shall embrace the usual branches of medical science taught in recognized medical colleges. The candidate will be required to show that he has an adequate knowledge of the Latin language and has received a good English education." The election of new members will hereafter take place at the annual meeting only.

A communication from the American Medical Association relating to State registration of medical practitioners, was referred to a committee consisting of Drs. A. E. Ham, Eugene Kingman, and C. V. Chapin, for consideration and future report.

Dr. E. T. CASWELL reported a recent case of litholapaxy performed on a man sixty-four years of age. Symptoms of bladder trouble had existed for over two years. Operation lasted one hour. There was no subsequent disturbance. The patient was out in a week, and able to retain urine four or five hours. The stone, which weighed 166 grains, wet, was composed of uric acid with phosphatic shell.

Medical Examiner W. H. PALMER, of Providence, exhibited an ossified ovary found at the autopsy of a young woman who died from heart failure due to fright two weeks after childbirth. The specimen measured 35.5 x 38 mm., and weighed 18.5 grams.

Dr. HERBERT TERRY read a paper on "Prevention of Lacerations of the Perineum during Childbirth," and exhibited a soft rubber spatula with a shank of thin steel, which had proved useful in distributing the pressure of the child's head uniformly over the perineum, thus preventing a rent in the median line.

Dr. G. D. HERSTY read a paper on the "After-treatment of Tracheotomy," considering only the care of patients upon whom the operation has been performed to relieve croup or diphtheria. Tracheotomy, in these cases, is only the first step in a tedious struggle with a

morbid process in the larger air channels; and our attention must be somewhat withdrawn from the first surgical procedure and turned to the diseased mucous surface of the trachea and the constitutional effects of diphtheria. The problem is to treat tracheal diphtheria after an artificial opening has afforded access to the middle and lower trachea.

In cases demanding this operation there is no clinical difference between croup and diphtheria. Recognizing the poisonous and debilitating nature of the disease we must expect to rely largely on stimulants and forced feeding. Milk, alcohol, ammonia, quinine, digitalis, and iron must be pushed to the utmost tolerance of the patient.

Whenever symptoms of obstruction occur, untie the tapes and remove the caudal, thus gaining an unobstructed access to the trachea and wipe out the frothy mucus with a swab firmly sewed to a flexible whale-bone stick. If there is abundant tough stringy membrane too firmly attached to the trachea to be separated by the swab, the curved forceps will be found a useful instrument.

During the first twenty-four hours following the operation the windpipe can probably be kept clear by these means. As the disease progresses more and firmer membrane is formed, filling the trachea and blocking up the tracheal end of the cannula. Violent strangling, cough, rapid respiration and pulmonary edema follow.

It is because this condition may come on a few hours after the operation and at any time for three or four days afterwards that the medical attendant or a competent trained nurse should remain constantly with the patient for four or five days and nights following tracheotomy.

Steam usually proves a prompt sedative for this excessive broncho-tracheal irritation. For this purpose steam atomizers and portable boilers are worthless. They frighten young patients and are wholly inadequate for producing the large volume of steam required. If the house is heated by steam, the pipe may be tapped and steam carried through a rubber tube to the bedside.

An efficient apparatus may be extemporized by arranging a tent over the bed and slacking line in a pail of boiling water within the tent. After five to ten minutes of hot steam, remove the tracheotomy-tubes leaving an open track into the trachea. Through this passage the surgeon may safely pass a dull copper curette and thoroughly scrape the surface of the trachea down to its bifurcation. By going carefully around the entire circumference of the windpipe and even dipping into the bronchi, if necessary, he will scrape out an abundance of tenacious fetid membrane and mucus which he must be prepared to catch the instant it appears at the mouth of the wound or it will be sucked in again with the first inspiration. The cannula or other apparatus for keeping apart the edges of the wound having been thoroughly cleansed and supplied with fresh tapes may then be replaced. The wheezing rapid respiration and strangling cough return, however, sooner or later, to be again relieved by the dense moist atmosphere of hot steam and careful currying of the trachea.

The first one hundred hours following tracheotomy is a period of treacherous and unexpected emergencies demanding the utmost vigilance on the part of the tracheotomist.

<sup>1</sup> See Vol. cxl, No. 29, November 13, 1884, p. 461, of this Journal.

Throughout the history of every case, absolute cleanliness of the patient, the wound, the canula and tapes must be demanded. The night dress and bedding must be changed as soon as soiled. Nowhere in medical or surgical experience is a faithful skilful nurse so absolutely necessary as in the care of a child who has received tracheotomy.

The process of sucking the wound with the surgeon's lips to remove mucus and floating membrane by a sort of aspiration, the writer considered more foolhardy than necessary. Steam, the dull wire curette, the curved forceps and the flexible whalebone swab or cotton-carrier can alleviate the most desperate cases, as the two following instances illustrate.

CASE I. A delicate boy of six years had diphtheria in the fauces and pharynx, followed by croup, and when cyanotic, tracheotomy was done. Hypodermic injections of brandy revived him and he went along well for three days. The writer was summoned hastily at sunset on the third day and found the boy exhausted by a recent struggle, unconscious, pulseless, making occasional feeble efforts at respiration, and rapidly dying from asphyxia. Three drachms of brandy were given hypodermically. The canula, in critical moments always an obstruction, being removed, the curette easily pulled out a large piece of tough membrane which, partially dried, had occluded the trachea and plugged the lower mouth of the canula. More membrane was scraped away with the curette, and half an hour later the moribund patient, re-suscitated, drank a wineglass of milk. He recovered.

CASE II. Tracheotomy was performed on a five-year old boy for diphtheritic croup. He did tolerably well for three or four days, and then the trachea and bronchi gradually filled with tough secretion and membrane, which the patient could not expect. Two attending physicians gave up the case as hopeless, and as the patient was choking to death, mercifully gave him ether for sake of euthanasia. The writer, who had been present at the operation by invitation, was sent for after the other physicians had left. The boy was speedily put into hot blankets, a tent thrown over his crib and filled with steam, and brandy administered freely both by hypodermic and rectal injections. Re-suscitation was slow, but the heart responded to the stimulus of alcohol, steam softened the gluey exudate and the curette cleared a passage to the lungs. Helped by prolonged steaming and occasional use of the curette the reviving boy coughed up considerable membrane and mucus, and in two hours sat up and drank milk punch. His convalescence was interrupted by an attack of pneumonia, yet he made a good recovery.

Probably neither of these lives would have been saved without the use of the curette. Referring to the hitherto unappreciated value of this instrument in the treatment of tracheal obstruction following tracheotomy, the writer said that he had employed it frequently and had never seen its use cause pain or hemorrhage or strangling.

A light-minded lay contemporary suggests as a suitable locality for hay fever patients Mount Carthage.

Among the topics planned for discussion by the Pharmaceutical Congress, sessions of which opened in Brussels on August 1st, is that of the proposed adoption of an International pharmacopoeia.

## Recent Literature.

*Face and Foot Deformities.* By FREDERICK CHURCHILL, C. M. Published by P. Blakiston, Son & Co., Philadelphia.

This book is a disappointing one. A casual glance at a few of its paragraphs suggests a medical counterpart of the famous Portuguese Grammar, "English as She is Spoke," which, endorsed by the high authority of Mark Twain, has attained to unexpected popularity.

But the work hardly rises to this dignity, though a few passages may be quoted as worthy of comment. Speaking of injuries of the face the writer adds, "there may or may not be symptoms of concussion; the child should be kept away from school, and have an evaporating lotion applied if there is pain." "He may have fallen down on a sharp stone, or some mischievous playmate may have thrust a knife or pointed instrument into the face, either purposely or accidentally, or the wound may be self-inflicted by playing with swords, guns, etc."

This is, of course, encouraging, and later we find another sentence of a different order of excellence. "The rapidly increasing desire of young ladies to obtain distinction at the competition examinations in science, mathematics, etc., will convince them far more than argument, of the *raison d'être* of that which I have been pleading for — the beautifully perfect structure of the foot, with its double arch, the bones being wedge-shaped, resembling the upper stones of an archway." The rest of the book, however, hardly justifies such a brilliant promise, and the reader has to content himself with a list of the skin diseases of the face, affections of the eyes, extracts from Adams on Club-foot, with the report of a few successful cases.

Perhaps Mr. Churchill in his next book will either give us less that is medical, and more pleasure in "English as She is Spoke," or more of the best surgery of the London Victoria Hospital for Children.

It would, however, be unjust to dismiss this book without due praise of what of excellence it offers. The illustrations are very good, and give an example of painstaking on the part of the publishers which is not too common. The introduction into surgical text-books of practical directions as to the treatment of birth-marks by the cautery will be of use, as well as the method of removal of a nevus from the nose. We are glad to see that the author recommends the use of plaster-of-Paris bandages as a means of fixation of club-foot after tenotomy; and in general, the ideas of treatment which he advocates appear to be in the main sensible.

— *Experto Crede.* The North Carolina Medical Journal speaking editorially of the American Medical Association, says: "We do not sympathize at all with the suggestion that a new national society should be formed. Secession is a costly business—it arrays good friends against each other, consumes valuable substance, and is so liable to end at last in striking colors you have pride in, and in grounding your arms to an enemy having the only advantage over you in being more numerous and better fed."

— The gouty patient, on contemplating a meagre meritocratic achievement, murmured sadly, "Little drops of water, little grains of sand."

## MILK, ITS PURITY AND LEGAL QUALITY.

At a time when the attention of the public is being so much directed to the question of the quality of the food and drink which it consumes, the composition and examination of that very important, much used, and greatly abused article of diet, called milk, becomes a subject of pressing interest, especially from its important bearing upon the health of our children and invalid population.

Probably there is not a city upon the continent where the entire milk supply as brought into the city receives a sufficiently vigorous inspection to make it reasonably certain that none but pure whole milk is being distributed to the consumers. Yet we have reason to believe that Boston has made a much greater advance in this direction than has any other one of the cities. The amount of work which a really efficient inspection of the entire milk supply of a great city would involve, is much beyond what the uninitiated would suppose. It would be nothing less than the examination, at the very least, of one sample daily out of every dairy of milk which is being supplied to the city, or upon an average, one sample for every ten gallons of milk. This would be for the city of Boston a daily examination of about 1,500 samples of milk. A really efficient inspection like this has thus far only been accomplished by certain single large dairy companies, such as that of St. Louis, Mo., and the Aylesbury Dairy Company of London, England. This last alone during last year, besides a vast number of milk samples inspected, had about 1,600 samples analyzed, that is, a number some twenty-seven times larger than was analyzed during the first twenty-five years existence of the Boston Milk Inspection Office, that is from 1859 to 1884. During 1884-85, however, some 1,000 samples of milk were analyzed at the milk office of the city, and a revolution was inaugurated in the quality of the milk supply of the city. During the present year, the appropriation of the office having been increased sixteen fold, a still greater number is being analyzed with a still improving effect upon the supply as sold in the city. Since a year past the large milk contractors who bring much the larger portion of

the milk into the city, have felt obliged to have all their dairies of milk inspected, and all such have been analyzed as upon such inspection were not judged to be certainly above the present legal minimum limit of quality, that is, of thirteen per cent of milk solids. It should be remembered that we have a double requirement for milk offered for sale in this State. It must not only be pure whole milk from healthy properly fed cows, but it must also be of not poorer quality than to contain at the least thirteen per cent of milk solids. It has been the experience of the present milk inspector for the city of Boston, Prof. J. F. Babcock, as given in a published report, that the healthy properly fed cows of this State, upon the average, give a milk containing 14.55 per cent of milk solids. Dr. B. F. Davenport, the late inspector for that city has reported that he found the average to be 14.50 per cent, while Prof. S. P. Sharples formerly inspector for Cambridge has reported that he found the average to be 14.49 per cent. Thus there seems to have been a common experience with these three experts who have probably had as large an experience as any in the State, that the milk of an average cow contains about 14.50 per cent of milk solids. It was also reported by Dr. Davenport that the common so-called "native cow" gave a milk which contained upon the average 13.75 per cent of milk solids, of which 5.80 per cent was butter fat, and that no sample fell below three per cent in fat. It would, therefore, seem as if the State in placing the minimum limit of thirteen per cent of milk solids, which is something over ten per cent below the actual average product of all the cows in the State, has drawn the line for marketable milk at a fair and just point for the public interest.

As milk has hitherto been sold by measure, a large yield of milk has been the characteristic cultivated by those breeding cows to produce milk for the market, while in cows for private family use quality has more especially been regarded. The result has been what should be expected. Certain breeds of cows have been produced which give enormous quantities of milk, but poorer than the average quality, while upon the other hand other breeds have been obtained which give milk of a very rich quality, but in more moderate quantity. The natural product from this selected breed of "skin-milk" cows should no more be tolerated than the artificially skimmed milk of the average cows. It is the product itself that should be condemned irrespective of the means by which it is obtained, for it is the same thing. Yet some do not seem to see the justice of this, but claim that the natural product of a cow, no matter how unmixed that cow may be, should always be allowed to pass as good, fair milk. That is, to make a quality of milk allowable if it be obtained by one method, which would be condemned if it was produced by another and more simple method. In short, to allow of it if it be only attained by a round-about method of selection in breeding the cow, but to condemn it if it be produced by the simple and direct use of the skimmer, or by "topping" as the milk trade has it.

It is to be noted, however, that many of those producers who keep the "quantity breeds" of cows for their market milk, keep also one or more cows of the rich "quality breeds" to furnish milk for use on their own tables.

The producers as men of business will naturally look out for the quantity of their milk, therefore it is necessary that the State or some other public authority require in the public interests that it also be of fairly good quality as well as the actual product of healthy, properly fed cows, and also that it be distributed to the consumers exactly of the same or average quality. Human nature and greed of gain is very much the same in the country as in the city, and milk needs the strong protecting arm of the law as well in the one place as in the other.

During the late session of the New Hampshire Legislature, certain persons attempted to have that State's standard reduced below that of thirteen per cent of milk solids as at present required, but they were not able to persuade the Legislature to commit that error. The French government uses this same standard in its calculations of the percentage of watering in milk. Most of the other States of our Union have made the mistake of placing their legal standard below that of fairly good whole milk, and have put it down to the level of the poorest known whole milk. The consequence is that such a quality of milk is about as good as the citizens of those States usually receive, while in our own State a more reasonable standard having been adopted, the average quality of the milk furnished to the people is much better than in the other States, and it is greatly to be hoped that the present high standard may ever be maintained.

#### THE HYGIENIC BENEFITS OF A SOJOURN IN MOUNTAINOUS REGIONS.

THE vacation season is hardly yet over, and at the principal mountain hotels of northern New England may still be seen the familiar faces of citizens who have for a time exchanged the busy town for the high land and the wilderness. Hay fever sufferers find here numerous stations which give them exemption from their malady, and where too, the microbe of malarial fever never penetrates; and if the tubercular bacillus, less shy of moderate elevations yet dreads high altitudes, the phthisically pre-disposed may find the atmosphere of the White Mountains sufficiently aseptic.

It is only within a few years that attention has been earnestly directed to the subject of altitudes in their relation to prophylaxis and cure of pulmonary consumption. Since the demonstration of the antimicrobial character of the atmosphere of lofty elevations has been made by Miguel and Freudenreich—microphytes being rare at 800 metres, and absolutely wanting at 2,000—greater interest has been attached to the localities in connection with the treatment of early phthisis, and residents of New England are awakening to the realization of the fact that they can obtain the advantage of a mountain climate without

going long distances from home. Less importance is, however, assigned to the mountain air treatment of phthisis in this country than in some parts of Europe; thus among the Swiss Alps we find at Davos, at Engadine, and at St. Moritz sanitary stations fitted up expressly for the phthisical, combining the comforts of a home with the benefits of an hospital, and here, in the midst of the glaciers, multitudes of consumptives spend the summer months. Clinical observations seem to favor this kind of hygiene, but certain conditions are essential to the realization of good results; the patient must be at the very inception of the disease, and the tuberculosis must be of slow evolution, the constitutional reaction must be vigorous, the appetite keen; the invalid ought, moreover, to be able to spend much time in the open air, and endure fatiguing marches; under such circumstances the circulation becomes more energetic, and all the tissues receive a more plentiful irrigation; the respirations first quickened, soon become stronger and deeper, with greater expansion of the thorax and lungs; the muscular and nervous systems improve in tone and vigor; the appetite and weight steadily augment. It is needless to say that mountain climates are contra-indicated in phthisis attended with fever; all authorities recognize this fact.

But while the quality of *asepsis* is of first importance, it is the fortifying action on the constitution which is chiefly sought in the climates of altitudes, and it is for this that the multitudes leave the towns for the seaside or mountains. With the majority of those who, a little "run down," seek in change of scene the needed recuperation, it may be a matter of indifference whether they summer at a maritime or high-land station. For coolness, purity and richness in ozone the climate of the Isles of Shoals may, in its bracing effect on the invalid, be equal to that of any altitude on the continent. Sea air, moreover, has traces of iodine and bromine which under some circumstances may have a stimulant and remedial action. The coolness which alike characterizes both climates is a hygienic element *par excellence*, being largely the cause of the tonic effects experienced.

But there is a notable difference with respect to barometrical pressure between maritime climates and the climates of high elevations. This pressure, at its maximum on the mountains, is at its minimum on the sea level, yet both the mountain and sea air seem alike to arouse the languishing functions. He who ascends Mt. Washington breathes rarefied air, the Star Island visitor breathes air which is relatively condensed, yet in both cases there is increased appropriation of oxygen, and increased elimination of the products of organic combustion with lightening of digestion and assimilation. The lungs in the one instance are in a more *active*, in the other a more *passive* condition. It is not only the fact that the Mt. Washington tourist takes longer, stronger breaths, but the expansion of the chest, the pulmonary ampliation and ventilation, are more complete than in the case of the visitor at the watering place. This implies a more energetic condition of the entire machinery of hematosis; the

force of the respiratory muscles is augmented: certain regions of the thorax, particularly the apices, which are sometimes called inactive regions, because ordinarily taking but a feeble part in the inspiratory expansion, are brought into exercise.

It would seem, then, that the air of altitudes has a specially invigorating effect on the respiratory apparatus and function; moreover, the lowering of atmospheric pressure tends, as Jaecoud has shown, to unload the viscera, producing relative anæmia of these organs — this would be of hygienic importance in states of hepatic, renal, cerebral congestion, etc. — while the peripheral circulation is enhanced, the blood-flow to the superficial parts being greatly augmented.

It might be hence inferred that for tired denizens of the sea-board cities, and especially for jaded professional men, a vacation season at the mountains must be of all hygienic measures the most useful. The present period of the year, when the hotels cease to be crowded, when the weather is cooler and the air no longer laden with moisture, when the forests and highlands are adorned with their matchless September pageantry, is a good one for the busy practitioner who has been unable to leave his practice during the prevalence of summer complaints.

But he who elects to spend his vacation in the mountains has something to do besides quartering himself at a comfortable hotel, lounging about drawing-rooms, now and then indulging in a game of whist, or reading the latest novel, and eating three full meals a day; that is, if he would derive the utmost physical benefit from the change. Remembering that sunshine is vivifying, he will seek the open air. He will become an active pedestrian, climbing the high peaks, exploring the deep ravines, penetrating the tangled forests, admiring here the rushing cascades, and there with baited hook tempting the trout in the quiet pools. He will abjure Ziemssen and commune with nature, endeavoring amid the wild and gorgeous scenery to obtain the mental repose and restoration which, after the cares and the worry of the busy year, he so much needs. We cannot do better than give our emphatic endorsement to what a recent writer has so well said: "When the busy citizen has grown weary under the pressure of study or work, and has lost his ability to eat or sleep, or to take pleasure either in present or anticipated comforts, let him visit the mountains, and inhale the electric air, forgetting for the moment his home cares and adapting his thoughts to the ennobling surroundings. The sojourn in a summer hotel is well and beneficial, but the journey on foot is better, since it gives incessant variety, and ever-changing themes of diversion. After a few days of marching he will cease to complain of sleepless nights or zestless meals, and will find the leathery steaks of the village inn more delicious than the choicest triumphs of the Parisian chefs. The pedestrian's tour is of high value to men of sedentary habits, giving them a valuable and needed change of habit, expanding their shrunken lungs, and teaching their limbs pliancy and strength.

It is pleasing to see so many of the undergraduates of the New England colleges taking up this form of exercise and visiting the mountains in small squads on active service. In course of time it may be that the White Mountains shall be as favorite walking ground as the Scottish Highlands or Swiss Alps now are, and that the nervous American energy may acquire a legitimate strengthening of solid Anglo-Saxon endurance."

#### MEDICAL NOTES.

— Dr. Simms writes to the *Polyclinic*: "The oldest patient I have ever treated for any form of acute venereal disease, presented himself at the Polyclinic suffering with five very characteristic chancroids, situated upon the glans penis and inner surface of the prepuce. He believes he contracted them from a water closet. However, upon questioning him, I find he has a young wife, who, he says, is affected with some disease of the genitals. The healing of the sores, while it has been favorable, has been unusually protracted. His age is seventy-five years."

— A correspondent thus writes: "Regarding the native treatment of diseases in India, one of the most curious things I ever witnessed was a half-clad native shouting through the streets of a country town: 'Does any one want back his sight? — one rupee only!' as if he were hawking fruits or sweetmeats; and to my astonishment, a patient soon presented himself to be operated upon for cataract. There and then, standing in the bazaar, the itinerant oculist took out his penknife and performed the operation in a few minutes, bound up the man's eyes, telling him to keep in the dark for a fortnight, received his fee of one rupee, and shouted his wares for more patients. The operation was almost unvaryingly successful; one instance among my servants being a woman of eighty, who had charge of my fowl-house, and had for many days been sightless, except to distinguish light from darkness, and who in this way was successfully operated upon." — *Chambers' Journal*.

— Judge Tucker recently gave his decision in the George S. Dunbar case at Pittsfield. The facts and testimony were reviewed at length in the decision. Dunbar was found dead on a lonesome street at ten o'clock on the night of July 1. By his side was a revolver with a long string attached to the handle. A loop on the handle of the pistol could be adjusted to raise the hammer of the weapon to half-cock; then, by holding the revolver in the right hand at the back of the head, putting the string under the right foot slightly raised, drawing it tight with the left hand and putting the right foot down sharply, the hammer would be worked to explode the cartridge. Dunbar was found shot in the back of the head, and there is a distinct mark of the string on the shoe he wore. He was worth in stock of the gas company, of which he was superintendent, and in other securities and real estate, about \$12,000. He had borrowed on these securities

\$22,000, nearly all of which he had lost in Wall Street speculations. His life was insured for a very large amount in regular life companies, assessment companies, fraternal associations and in accident policies. Judge Tucker finds that the evidence compels him to believe that Dunbar committed suicide.

—Governor Robinson has made the following nominations for the Board of Registration in Pharmacy, established by act of the Legislature the past winter:

Samuel A. D. Sheppard of Newton, five years; Henry W. Whitney of Lawrence, four years; Freeman H. Butler of Lowell, three years; John H. Manning of Pittsfield, two years; Henry A. Estabrooke of Fitchburg, one year; of these Mr. Sheppard is treasurer of the Massachusetts College of Pharmacy and Mr. Butler is a trustee of the college. The others are in no way connected with it and none of them are graduates from it. All of the gentlemen nominated are in business for themselves, and have had from ten to twenty years' experience. Mr. Estabrooke, the youngest, is thirty-five years old; none of them are aged men. The portion of the trade that was especially active in behalf of the bill last winter is represented on the board, and also those who took no active part in its establishment. The board will hold its first meeting for organization on the first Tuesday in October.

#### BOSTON.

—Free vaccination is being performed at the Charity Building on Chardon Street, under the auspices of the Boston Board of Health. The employees of the Boston & Lowell Railroad are also being generally vaccinated, on account of the prevalence of the small-pox in Montreal. The sleeping-cars are not run through from Boston to Montreal but the passengers are obliged to change cars near the Canada line.

—A successful fair in aid of the Carney Hospital was held at the building of the Massachusetts Charitable Mechanics' Association in Boston, September 3. The spacious floors were none too large to accommodate the crowds who attended to show their interest in this cause; and we understand that a substantial pecuniary result was achieved.

—A serious epidemic of diphtheria occurred late in the season at Hotel Wellesley, which has necessitated the closing of the Hotel. Several deaths have occurred among children who were guests of the house. It is fair to say that the management have published certificates from several sanitary experts, based on very recent examinations, as to the absence of any defects of plumbing.

#### NEW YORK.

—It is to be hoped that the Board of Health will promptly take measures to remedy the unsavory condition of affairs at Fulton Market, the great fish depot of the city, as recently revealed by Mr. Bergh, President of the Society for the Prevention, etc. In a communication to the Health department, he calls attention to the filthy state of the basin in front of the market,

in which the fish awaiting sale are kept, as follows: "This basin, which extends the entire front of the market—say, 200 or more feet—is flanked on either side by lengthy piers, which, as may be supposed, almost wholly impede the flow of tide in the river. Into this foul enclosure, as if the stagnant pool were not sufficiently foul already, empties one of the great sewers of the city, added to which the daily excrements of the Union Ferry Company's closets, including the general use of that locality for like purposes by the vagrants of the neighborhood, unquestionably render that reservoir the most unfitting place that can be found to store food for human consumption. And yet, in this disgusting receptacle are to be counted hundreds of enormous crates, holding millions of fish annually, which are eaten by our inhabitants."

—One of the inspectors of the Board of Health (not a medical man), has been sentenced to three months' imprisonment for asking and accepting a bribe.

#### PORTLAND.

—The lecture term of the Medical Department of Bowdoin College has been lengthened to twenty weeks, and the next session will begin on the 1st of next February, closing on the 24th of June. By this arrangement, the closing exercises will occur on the day before the College commencement.

A chair of Public Hygiene has been established, and will be filled by Dr. A. G. Young, the Secretary of the Maine State Board of Health.

—Prof. Henry Carmichael, Ph.D., who has occupied the chair of Chemistry since 1873, has resigned, and Prof. Franklin C. Robinson, for some years the chemist of the College, is to succeed him.

### Dissealup.

#### A SUBSTITUTE FOR SENECA.

Of all the well-marked expectorants which are used in the treatment of cases of emphysema, senega root occupies the first place; and although not only here, but in the second stage of acute bronchitis, in chronic pulmonary catarrh, and the later stages of pneumonia, it produces often valuable effects, it unfortunately has a very bad taste, is expensive, and often produces intestinal irritation. Dr. K. Kobert (*Centralblatt für klin. Med.*) has found that this drug contains two glucosides which are in different proportion in different specimens of this drug as found in the market, and he has further found that in the quillaja bark (*Quillaja saponaria Molina*) these two glucosides are present, and in almost five times the proportion in which they are found in senega; and since this quillaja bark is ten times cheaper than senega root, the same amount of active substance is fifty times cheaper than in the case of senega. Moreover, the amount of glucosides present is a constant one, and the bark contains a considerable quantity of sugar, which gives the decoction a sweet taste, and which renders it further free from the disagreeable taste of the senega decoction. On these grounds, Dr. Kobert was naturally led to test its employment therapeutically; and the results of numerous observations have shown

him that patients bear this article better than senega, that it very seldom produces vomiting or diarrhoea, that the sweet taste leads to its being readily taken by children, while its expectorant action stands beyond all question. The mode of administration which he employed is in the form of a decoction of five parts of the bark to two hundred of water, taken by the tablespoonful by adults and the teaspoonful by children. Dr. Kobert states that ulcers, or inflammation of the intestines or stomach are contraindications for the use of this drug, since its rapid absorption by portions of the intestinal tract which have lost their epithelial coating may readily produce symptoms of poisoning. If taken dry, even when mixed with sugar, the powder nearly always produces coughing. It is to be hoped that these results will be generally tested, as a powerful and safe expectorant is certainly greatly needed.—*Therapeutic Gazette*.

### THE TREATMENT OF SOME FORMS OF DIARRHÆA.

THE editor of the *Therapeutic Gazette* (August 15.) gives some timely suggestions as to the treatment of diarrhæa.

The first of these is as to the value of sulphuric acid in the treatment of diarrhæas of relaxation. "Many years ago," he says, "we learned from the late Prof. Francis Gurney Smith the value of this remedy, especially in combination with the extract of hamatoxylin. The following prescription we have tested almost innumerable times. It makes a very agreeable and efficient mixture, and may be given if necessary every two hours. Of course it should be varied, especially in the opium it contains, to suit individual cases.

R Acid, sulphur. aromat., f ʒ iii;  
Extr. hamatoxylin, ʒ iii;  
Tr. cinnamon,  
Tr. opii camph., ʒi f ʒ iiss;  
Syr. q. s. ad f ʒ xli. M.  
S.—Tablespoonful, as required, in a little water.

A second remedy, still less frequently used than sulphuric acid, but of great service in non-inflammatory diarrhæas, is carbolic acid, or, perhaps preferably, creasote. This remedy is especially useful in cases of lenty, with which there is such excessive nervous irritability of the bowels that food when taken passes right through. But it is also often very serviceable in ordinary summer diarrhæas. A very valuable combination, useful especially in sudden violent attacks, is afforded by the following prescription. It may be administered every half-hour at first; of course care must be exercised not to give the maximum dose too frequently.

R Chloroform, f ʒ iiss;  
Ol. eucalypti, ʒ i;  
Creasote, ʒi f ʒ i;  
Tr. opii, f ʒ iiss. M.  
S.—Shake well. Dose, 20 to 30 drops

In some cases, especially of more chronic or persistent diarrhæas, of which we have been speaking, where there is excessive acidity of the intestines, a combination of creasote with chalk or bicarbonate of sodium is very useful. Not rarely the addition of the creasote to an ordinary astringent cough-mixture affords excellent results.

In regard to dysenteries, there are only two remedies which have in our hands given satisfactory results. One of these is calomel, and the other ipecacuanha. Of the two the vegetable drug is the more universal in

its application, although in the sporadic dysenteries, as seen in this climate, calomel is usually efficient. The objection to the use of ipecacuanha is the distressing vomiting which it is so prone to produce. The amount of vomiting is, however, very greatly affected by the method of administration. Some practitioners are accustomed to begin the treatment of dysentery by a large dose of the ipecacuanha in powder and endeavor to obtain tolerance after repeated vomiting. We have found that in many cases, vomiting can be altogether avoided and the desired results achieved by giving the ipecacuanha in doses of five grains every half-hour, in pill form in combination with opium, or, better, by preceding each pill fifteen minutes by a dose of opium. In very bad cases with pronounced so-called bilious symptoms,—that is, excessively-coated tongue, epigastric tenderness or sense of weight, sick stomach, and vomiting,—it is probably preferable to begin the treatment by giving the five-grain pills every fifteen minutes until free vomiting is set up."

### INCISION OF THE PERICARDIUM IN PURULENT PERICARDITIS.

At a recent meeting of the Moscow Russian Medical Society, Dr. Ekaterina A. Mikhailova communicated (*Meditz. Obozr.*, Fasc. v., 1885) an interesting case of purulent pericarditis of traumatic origin, treated by tapping and incision of the pericardium, which is summarized in the *London Medical Record*, August 15.

The patient, a cook, aged 35, who had for many years suffered from cardiac palpitation and rheumatic pain in the right side of the chest, was admitted to the Staro-Ekaterinsky Hospital five days after a fall from considerable height. For the first day after the accident, the patient had remained in an unconscious state; on return of consciousness on the second day, she had tried to get up and to resume her usual work, but had found herself unfit for anything on account of giddiness and intense attacks of palpitation.

On admission, she looked pale, anemic, and exhausted; the tongue was whitish, moist; pulse small, 90; temperature 39° C. The chest was normally developed, its excursions being equal on both sides, though not energetic. The apex-beat was not visible, and hardly perceptible to the touch. The cardiac dulness commenced from the third rib; its left border passed slightly beyond the nipple line, the right reached the median line, and the lower extended downwards to the sixth rib. The heart-sounds were feeble, but otherwise normal. A dull area was detected over the posterior aspect of the right side of the chest, extending from the scapular angle down to the lower border of the lung. Auscultation revealed there cutbelled vesicular respiration. The patient could not lie on her right side, on account of dyspnoea being increased.

For the next eight days, the patient's state remained much the same; on the ninth there appeared intense dyspnoea, and cyanosis of the lips and nose; the pulse became much smaller and intermittent, 120; the urine contained much albumen, pus-corpuscles, and hyaline casts. On examining the patient on her back, the cardiac dulness now commenced from the lower edge of the second rib, extended on the left to the anterior axillary line, and went on the right slightly farther than the right edge of the sternum, the lower border remaining at the sixth rib. The apex-beat could not be felt

any more: the heart-sounds were clear, but very feeble and intermittent. On the fourteenth day, oedema of the subcutaneous tissue in the præcordial region was noticed.

The cardiac symptoms steadily growing worse, on the fifteenth day aspiration with Dieulafoy's apparatus was performed in the fourth intercostal space, and 120 cubic centimetres of fluid drawn off. The first 80 cubic centimetres consisted of pure cream-like pus, the remaining 40 almost entirely of blood. Immediately after the puncture, the patient was in a state of semi-collapse, but on the next day there was noted a slight improvement in the subjective symptoms. On the seventeenth day, the cardiac dullness reached up as far as the clavicle, the pulse became scarcely perceptible, the dyspnea extreme; the lungs were full of mucous râles. To satisfy the vital indication, incision of the pericardium was decided upon and performed by Drs. P. P. Minin and Hindenburg. It measured about two centimetres in length, its spot being close to the left edge of the sternum, in the fourth intercostal space. About two fluid pounds of fetid blood-stained pus escaped. After washing out the pericardial cavity with boracic water (at 38° C.), a drainage-tube was inserted, and the carbolic gauze applied. Striking relief immediately followed; the dyspnea diminished, the pulse became regular and 90; the cardiac dullness normal. However, in spite of three successive subcutaneous injections of ethereal tincture of valerian, the cardiac action remained low, and eighteen hours after the operation the patient died.

Analyzing the details of the case, Dr. Mikhailova arrives at the conclusion that she had to deal with an instance of idiopathic purulent pericarditis caused by injury. Pointing to the fact that in her case (as in the case of Partzovsky, for which see the *London Medical Record*, Feb. 1883, p. 33) the operation was resorted to too late, the author states her belief that incision of the pericardium in cases of purulent pericarditis may be followed by a favorable issue only when it is undertaken in presence of a healthy cardiac muscle. On the other hand, however, she seemingly admits Professor Rose's dictum that, as a rule, incision of the pericardial sac in purulent pericarditis has the same therapeutic value as tracheotomy in certain affections of the respiratory organs.

At the *post mortem* examination, there were found fatty degeneration of the cardiac muscle, dilatation of the cardiac cavities, considerable old fibrous thickening of the pericardium, fibrino-purulent exudation, with admixture of blood in the pericardial sac, right hydrothorax, total obliteration of the left pleural cavity, oedema of the lungs with purulent bronchitis, marantic thrombosis of the pelvic veins, and of the vena spermatica interna dextra, ischæmic necrosis of the right kidney; the same, but in a less advanced stage, in the left kidney. A search for bacilli in the heart and pericardium gave negative results.

#### PAINLESS EXECUTION.

CAPITAL punishment possesses some Circæan attraction for the amateur philanthropist. Those who are not prepared to abolish it altogether, are anxious to so modify its methods as to replace the deterrent image of grim death by the almost seductive oblivion of a judicial euthanasia. To this end the mysteriously sub-

tle power of electricity has been oftentimes invoked. An English surgeon recently recommended that as the condemned criminal left his cell "a powerful current should be turned on" to a brass plate let into the floor of the corridor, so as to substitute a rapid and painless demise for the horrors which have now and again even recently disfigured the ghastly operations of the hangman. The idea was doubtless conceived in a kindly spirit, but the directions are too vague to be of much practical value; and good authorities are as doubtful as men who have not themselves submitted to the *experimentum crucis* can well be, as to whether death by electricity is by any means the painless process which the popular mind conceives. A more merciful method is suggested by an American physician, who suggests the "hypodermic administration of morphine as a substitute for hanging in the execution of criminals"; taking the ground that while hanging is often rapid and painless, it is sometimes slow and cruel; and being of opinion that the medical profession should suggest to the State a method of killing free from objectional features. This last idea is, we fear, impossible of realization. The morphine plan would certainly fulfil some of its requirements; and it is scarcely probable that the most calculating criminal would set to work to contract and foster the "morphia habit" with the view of rendering himself physiologically unable to pay the last debt of justice in the manner legally prescribed. But it is not well that any suspicion of secrecy should enter into the administration of public justice; and the law of this country would assuredly and rightly look askance at the suggestion that it should even seem to adopt the methods of the poisoner.—*Medical Times and Gazette*.

#### AGAINST THE WET-NURSE.

DR. SAMUEL S. ADAMS, of Washington, argues in the *Archives of Pediatrics* strongly against the current medical opinion that a wet-nurse is the best substitute for a mother in bringing up a child.

He speaks of the low moral tone of most of the women obtainable, who at best, seek such a position in order to make money, abandoning for that purpose their own children. In case of twins, the supply of milk afforded is insufficient and a constant excitation of the lactal glands, while perhaps increasing the secretion, diminishes its quality. The difficulty of being sure of the physical health of the woman is referred to, and the temptation to an easy fraud in passing off when examined by the physician, a healthy borrowed child for her own sickly one, as evidence that the milk is of good nutritive quality. The writer continues: "She (the nurse) must be temperate, of gentle disposition, neat and cheerful; so she may be when she is nursing the foster-child if some one is watching; but once out of sight, how are we to know what vices she may not indulge? She must be of a loving disposition. If she have such a disposition, is it not reasonable to suppose that her own child will be her first care? If she do not love her own, she may, and probably will, tuck it snugly away in a basket on somebody's doorstep, or put it in a foundling asylum. If she does this with her own, how can we expect her to be gentle, kind, and loving with another's?"

"Supposing, however, that we could control her moral nature and habits, is it not more probable that her suf-

ferings will be very great? She may not live near the foster-child, and in that case must undergo the fatigues of paying frequent visits to each infant. It is not reasonable to expect that such a woman will allow her own offspring to suffer, and consequently it is more than likely to get the lion's share of milk, while the foster-child is permitted to suffer and become puny and sickly. If she is carefully guarded, and the foster-child gets its full supply, rest assured the little one at home spends sleepless nights, and pines and sickens. Does not this naturally produce anxiety of mind and loss of rest, and impair the nutritive value of her milk?

"It may be claimed that my objections do not hold with regard to a woman who has lost her own child. This may, in a measure, be true; but even in these cases, there remains the uncertainty as to antecedents and many of the other objections heretofore mentioned, and these impel me to the selection of cow's milk as the best substitute for the mother's, and as offering the surest guarantee against transmissible vices of constitution and the many unknown and unknowable dangers of wet-nursing, even in its best form.

"We are told that a wet-nurse's diet should not be changed; that if she has been accustomed to coarse food, a change to rich and highly-seasoned diet will disturb digestion and thereby render her milk harmful. It is difficult, if not impracticable, to keep a close watch over her diet, and every one knows how great is the temptation to indulge in rich and highly-seasoned food on the part of those who are accustomed only to the commoner and coarser varieties."

#### BURIED SUTURES.

MR. C. B. KEETLEY describes under this head sutures which are completely covered by the skin, and do not involve that structure at all; they are strongly recommended to be used in all operations in which deep structures are involved, and where rapid union is required. The use of these sutures enables operations such as excision of the hip to be performed without the use of drainage-tubes in the after-treatment of the wound. The method of applying these deep sutures is thus explained by the author. Suppose an operation to be performed with the object of uniting the two ends of a deep nerve that has been divided. After the ends of the nerve have been united, whatever muscles or aponeuroses had been divided in cutting down upon the nerve would be restored to their original relationships, and kept there by aseptic animal sutures; then the wound in the deep fascia must be separately sewn up, and finally the wound in the skin must be closed with catgut, or silver, or whatever is preferred. The results to be expected from this method of procedure are these:—

- (1) There is no need for drainage-tubes.
- (2) The sutured muscles and aponeuroses are eventually restored as regards functions.
- (3) Deep, rough, and depressed cicatrices are avoided.
- (4) Necrosis of bone and sloughing of soft tissues are avoided.

The author also states that he has found these sutures very successful in dealing with sebaceous cysts of the head. Having dissected out three from the scalp of a gentleman, the remaining cavities were obliterated by two sutures in each, passing them well through

the floor of each small wound. No cutaneous sutures were used at all; the skin-wounds did not gape. A little salicylic acid dissolved in ether, and a little powdered salicylic acid, were placed over the wound. The patient went about his usual business, and a fortnight afterwards the scab was removed, leaving three sound linear cicatrices. — *British Medical Journal*, May 2, 1885.

#### THE EXTERNAL TREATMENT OF NIGHT-SWEATS.

The *Therapeutic Gazette* (August 15,) remarks concerning the treatment of night-sweats by external applications, that Nicolai (*Gazette Médicale de Paris*, June 6, 1885) obtained very good results in the case of night-sweats of phthisical patients, and others, by the employment of eight grammes of chloral dissolved in two tumblersful of a mixture of equal parts of brandy and water. Every evening before going to sleep, the patients are washed off with a sponge soaked with this solution, and if that does not serve to control the sweating, the shirt in which the patient sleeps is soaked with the same solution and then dried. The effect of this treatment is claimed to be especially satisfactory in cases of children, not suffering from phthisis, in whom night-sweats are present. Sometimes four rubbings with this solution are sufficient to entirely arrest the night-sweats for several weeks.

The tincture of belladonna is also highly recommended by Radakow for the suppression of the night-sweats of phthisis by external friction with a mixture of four grammes of the tincture of belladonna with thirty grammes of water, the friction to be made about two hours before the ordinary onset of the sweating. The fluid is to be poured into the palm of the hand and then rubbed over the entire body, with the exception of the head and the extremities, and the manipulation may be continued until the skin becomes quite moist. This treatment has been employed by Radakow in fifty cases, and he claims that it has not failed in a single instance, although sometimes localized sweatings appeared on the parts which had not been bathed with the tincture of belladonna.

#### JAUNDICE AND PAIN IN BILIARY COLIC.

Mr. Lawson Tait, in the *Lancet*, July, 1885, offers some suggestions as to the reason why, during the passage of gall-stones, there is frequently no jaundice. In fifteen cases of cholecystotomy there has been no history of jaundice, and Mr. Tait has found that the occurrence of jaundice, either in the skin or in the urine, during and after the passage of gall-stones, is of extreme rarity, and not, as has been believed, common. Mr. Tait believes that the explanation of his fact lies in the following anatomical conditions of the cystic and common ducts. The common duct is not so long (3 inches) as most text-books assert, and is much less rigid and more easily dilatable than the cystic duct, which is larger than as usually described, namely, one inch. Hence, we can understand how a stone, if not of very great size, will cause intolerable agony while passing through the unyielding cystic duct, and without a trace of jaundice ensuing, the gall-bladder alone being its propellant force; but the moment it enters the common duct the extending impulse will be increased by the influence of the whole excreting force

of the liver, so that its passage through the common duct is more rapid. The chief symptom then, that of pain, is due to the slow passage of the calculus through the myeloid cystic duct, whilst its rapid passage through the easily distended and much larger common duct gives no time, in the majority of instances, for the production of jaundice, which only takes place after long-continued obstruction of this the common duct.

#### FATAL POISONING BY WHITE PRECIPITATE.

POISONING by means of the Ammonio-chloride of Mercury (White Precipitate) is rather rare. The following case is therefore of interest. It is reported by E. Head Moore (*British Medical Journal*).

The patient was a man of fifty-two years, who had been intemperate but had for many months totally abstained from alcoholic drinks; but on the occasion of his wife giving birth to a dead child, the pressure of grief (?) proved too much for him, a protracted spree being the result. When in this inebriated condition, he "took some acid he had from his battery," which proved to have been only a few drops of sulphuric acid, which caused no bad symptoms; but he took, also, about forty grains of white precipitate. He was found suffering great pain, vomiting food freely, with cold clammy perspiration; pulse soft, feeble and rapid; bloody stools, and anxious expression.

There was none of the specific effects of mercury apparent, the symptoms being purely those of an irritant poison. The treatment consisted in frequent doses of white of egg, which was generally quickly vomited, and doses of five minims of tincture of opium with ten minims of tincture of hamamelis, every quarter of an hour, which appeared to allay both the pain and vomiting. The patient, however, never rallied, and died in about five hours after taking the poison.

### Correspondence.

#### THE QUESTION OF A VITAL PRINCIPLE.

MR. EDITOR.—As Dr. Prince boasts of having gained his ideas from men eminent for their knowledge, it is remarkable that in his reply to my paper he should have confined himself almost entirely to simple denial and to abuse. I stated in my paper that I did not intend to discuss the nature of the vital principle in the different orders of living beings but merely to show that there is one; that is to say, something besides matter pure and simple. I fail to see why this should make the task of disproof more difficult, the question being simply whether material forces are, or are not, sufficient to account for vital phenomena. Although Dr. Prince announces that he shall discuss the most essential principles involved, the only part of his reply that is at all argumentative is directed against my first proposition founded on the unity of living organisms and especially against the point that there is absolutely nothing in matter to account for the phenomena of growth, reproduction, etc. Dr. Prince remarks: "It is one of the canons of science, that we must not multiply causes without showing the inadequacy of existing ones. Before, then, introducing a vital principle to account for vital phenomena, we must show the impossibility of material forces producing these results." This is true and well said. It enables us to come at once to a definite issue.

My proposition is stated in the following syllogism:

Essentially contradictory phenomena (like any other effects) cannot have a common cause.

The phenomena of living and non-living matter are essentially contradictory.

Therefore they cannot have a common cause.

If these premises be granted the conclusion cannot be denied. No one, I think, will dispute the first premise. To do so would be to destroy physical science. The validity of the second premise, that vital and non-vital phenomena are contradictory is, I conceive, the point at issue. The following are some of the respects in which living and non-living matters differ essentially.

(1) *Non-living matter* once at rest remains so till disturbed by some external influence. When in action it tends to transmit its energy to other matter. *Living matter* does not remain at rest, it moves by internal agency and much, probably most, of its activity is exerted on itself.

(2) *Non-living matter* is the same throughout. *Living matter* has distinct parts with particular functions.

(3) *Non-living matter* grows only by accretion, the addition of similar particles. *Living matter* grows by assimilating foreign substances.

(4) *Non-living matter* remains unchanged. *Living matter* grows, becomes old and dies, presenting a regular cycle of changes.

(5) *Non-living matter* cannot reproduce its kind. *Living matter* can.

(6) *Non-living matter* suffers from the influence of the external world. The magnet loses power by use, water wears away the rock. *Living matter* is benefited by action if not excessive. The brain, the eye, the ear gain power by use. Even the resistance of the outer world makes bone, muscle and skin stronger.

Other important distinctions might be mentioned, but these are sufficient to establish the minor premise, and that being done the conclusion is inevitable, that vital and non-vital phenomena cannot have a common cause. The forces of matter being sufficient to account for non-vital phenomena, it follows that something else than matter is needed to account for the vital ones. This shows the impossibility of Dr. Prince's theory, which seems to be that greater complexity of activities can bring forth effects of a higher order, such as (according to his theory) a more complicated watch might think, or perhaps under favorable circumstances, reproduce little watches. Dr. Prince tells us that: "The fact that certain phenomena are observed associated with matter is *prima facie* evidence that these phenomena are due to the forces inherent in matter." I should be glad to know why. Put into syllogistic form his proposition is as follows:—

Phenomena are due by *prima facie* evidence to forces inherent in that with which they are associated.

Vital phenomena are associated with matter.

Therefore they are by *prima facie* evidence due to forces inherent in matter.

Let us change the minor term and see what results. For instance, the phenomena of motion are associated with a machine.

Therefore they are due by *prima facie* evidence to the forces inherent in the machine, or, the phenomena of uniforms are associated with soldiers, therefore they are by *prima facie* evidence due to the forces inherent in soldiers.

Dr. Prince declines to discuss my second argument based on sensation, observing, truly enough, that it would take too much space. This evasion of it, however, is hardly consistent with his promise to discuss "the most essential principles involved."

The third argument, based on the freedom of the will, he dismisses with a sneer. This is not surprising, as he must know it is unanswerable. Whatever some men may say in their writings, no one in practice doubts the freedom of the will. What man does not know that he is free to reply to an adversary or not? Who does not choose his arguments knowing that he is free to take one and to reject another? The fact of the freedom of the will is as certain to our consciousness as that of any objective phenomenon. It cannot, however, be reconciled with materialism and

with various theories of the day by which the half-educated are deceived. As the argument cannot be answered it must be ignored.

I would say, in conclusion, that if Dr. Prince felt called upon to take the part of Professor Hammond, he was bound to show some fallacy in my criticisms. He may have thought, however, that the expressed opinion of the author of "*The Nature of Mind and Human Automatism*" is in itself so conclusive as to render demonstration superfluous.

THOMAS DWIGHT.

P. S. After the above had been sent to the *Journal*, my attention was called to Mr. John Fiske's latest work, "*The Destiny of Man*," from which I beg leave to make one or two short extracts, in refutation of Dr. Prince's confidence that he represents modern science.

"That it (consciousness) cannot possibly be the product of any cunning arrangement of material particles, is demonstrated beyond peradventure by what we now know of the correlation of physical forces," p. 42.

"The only thing which cerebral physiology tells us, when studied with the aid of molecular physics, is against the materialist as far as it goes. It tells us that during the present life, although thought and feeling are always manifested in connection with a peculiar form of matter, yet by no possibility can thought and feeling be in any sense the products of matter. Nothing could be more grossly unscientific than the famous remark of Calanis, that 'the brain secretes thought as the liver secretes bile,'" p. 109.

"Viewed upon this side, (the metaphysical one) it is easy to show that Atheism is very bad metaphysics, while the materialism which goes with it is utterly condemned by modern science," p. 13.

# HELMHOLTZ'S PHYSIOLOGISCHE OPTIK. ITS BIBLIOGRAPHY.

At the request of Dr. Henry D. Noyes, of New York, we give insertion to the following request for contributions to the bibliography of the new edition of "*Helmholtz's Physiologische Optik*."

BERLIN INSTITUTE OF PHYSICS, August 6, 1885.

Dear Dr. Noyes, — If I remember rightly, I told you at our last meeting, which I recollect with great pleasure, that a new edition of the "*Physiologische Optik*" of Prof. Helmholtz, was being prepared. At present, the work of printing has begun. The bibliography will be printed last and in a separate chapter. It is to be enlarged and to be brought up to the present time. At the request of Prof. Helmholtz, I have taken charge of this part of the work. On account of the enormous increase of the literature of physiology during the last twenty-five years, it is very difficult to make it complete. In order to be as thorough as possible, I have published a request asking authors to favor me with a notice of their publications relating to physiological optics. This has appeared in several French and German ophthalmological journals. Would you have the kindness to procure the insertion of a similar call in some of your American journals?

My address, to which letters may be sent, is Dr. Arthur Koenig, No. 16 Neue Wilhelm-Strasse, Berlin.

Any communications on the above subject will place me under great obligations.

Most sincerely yours,

ARTHUR KOENIG.

## REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 12, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 1,774: under five years of age 730; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 464, diarrheal diseases 428, consumption 254, lung diseases 100, diarrheal diseases 236, typhoid fever 52, diphtheria and croup 74, whooping-cough 23, malarial fevers 20, cerebro-spinal meningitis 10, scarlet fever five, puerperal fever two, measles two, smallpox one. From whooping-cough, New York 14, Philadelphia and Providence two each, District of Columbia, Worcester, Fall River, Holyoke and Chelsea one each. From malarial fevers, New York 11, District of Columbia four, Philadelphia three, New Haven and Charleston one each. From cerebro-spinal meningitis, New York six, Fitchburg two, Philadelphia and Fall River one each. From scarlet fever, New York, Boston, Charleston, Gloucester and Waltham one each. From puerperal fever, New York and Philadelphia one each. From measles, New York and Providence one each. From smallpox, Boston one.

In 109 cities and towns of Massachusetts, with an estimated population of 1,320,533, (estimated population of the State 1,555,104), the total death-rate for the week was 18.16 against 17.19 and 18.27 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending August 29th, the death-rate was 18.4. Deaths reported 3,133; infants under one year of age 197; acute diseases of the respiratory organs (London) 201, diarrheal 374, measles 89, whooping-cough 85, fever 49, scarlet fever 27, diphtheria 23, smallpox (London five, Manchester one) six.

The death-rates ranged from 13.7 in Bolton to 27.5 in Preston; Birkenhead 19.6; Birmingham 17.9; Bradford 17.3; Hull 17.4; Leeds 18.6; Leicester 14.6; Liverpool 20.3; London 17.5; Manchester 21.5; Sheffield 18.1.

In Edinburgh 16.0; Glasgow 21.2; Dublin 20.1.

For the week ending August 29th in the Swiss towns there were 32 deaths from diarrheal diseases, consumption 28, lung diseases seven, whooping-cough four, typhoid fever two, diphtheria and croup one. The death-rates were: at Geneva 12.1; Zurich 9.7; Basle 12.1; Berne 24.0.

The meteorological record for week ending September 12th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 12, 1885, TO SEPTEMBER 18, 1885.

CAMBERELL, JOHN, colonel and surgeon. Retired from active service September 16, 1885. S. O. 212, A. G. O., September 16, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING SEPTEMBER 19, 1885.

MURRAY, J. M., post assistant surgeon. Resignation to take effect January 1, 1886.

ROSS, J. W., surgeon. To special duty at New York.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE FOUR WEEKS ENDING SEPTEMBER 19, 1885.

AYSTANT, JOHN, surgeon. To proceed to New Orleans, La., September 16, 1885.

BELLON, W. H. H., surgeon. When relieved, to proceed to Mobile, Ala., September 16, 1885.

LOVE, W. H., surgeon. Granted leave of absence for ten days, September 1, 1885. When relieved, to proceed to Detroit, Mich., September 19, 1885.

LESTRADE, C. S. D., surgeon. To proceed to Norfolk, Va., September 16, 1885.

SAVILL, H. W., surgeon. When relieved, to proceed to San Francisco, Cal., September 18, 1885.
